- Play helps develop a child’s language and cognitive skills, as well as social competence.
- Experiences affect children’s motivation and approach to learning (e.g., persistence, initiative, flexibility).

Along with best practices, the following NAEYC guidelines list five key and interrelated areas of practice for early childhood professionals’ decision making:

1. Creating a caring community of learners
2. Teaching to enhance development and learning
3. Planning curriculum to achieve important goals
4. Assessing children’s development and learning
5. Establishing reciprocal relationships with families (NAEYC, 2009)

Important Issues in Educating Early Childhood Teachers

Constructivism

Some authors state that any discussion of best practices in early childhood education would be incomplete by not addressing constructivism or constructivist learning. Although not a theory of

teaching, constructivism is a theory about knowledge and learning, and serves as the basis for many current reforms in education, according to Jacqueline Grennon Brooks and Martin Brooks. In opposition to more traditional views of education, constructivist learning allows schools to implement practices that encourage students to think, rethink, demonstrate, and exhibit their knowledge or understanding. Traditional educational process tends to emphasize either rightness or wrongness; however, with the constructivist model these divisions are no longer helpful. The constructivist classroom offers a new approach to what goes on within schools.

The National Science Teachers Association calls for education reform based on hands-on experimentation, learner-generated questions, and investigations. This description matches well with NAEYC's best practices listed above.

Learning through a constructivist perspective is a self-regulated process with the learner resolving cognitive conflicts by way of concrete experiences, collaborative discourse, and reflection. This is an eloquent description of early childhood education's focus on how children learn and puts the learner in charge. Constructivist pedagogy brings a view of the student as thinker, creator, and constructor, highlighting many educators' and parents' concerns with the current campaign in the United States focusing on universal standardized curriculums and assessment. Five overarching principles to constructivist pedagogy are offered:

1. Posing problems of emerging relevance to learners
2. Structuring learning around "big ideas" or primary concepts
3. Seeking and valuing students' points of view
4. Adapting curriculum to address students' suppositions
5. Assessing student learning in the context of teaching (Grennon Brooks & Brooks, 1993, p. viii)

Again, with these principles it is clear that the students are placed in the forefront of the education process. With constructivist education, students come to understand that they are responsible for their own learning within an environment that follows these principles. This view of education is in opposition to the habitual rehearsal approach to learning so often found in elementary teacher training programs and school classrooms—where the education focus more closely fits the "what children should be taught" philosophy. Basic to creating environments that support constructivism, teachers must become constructivists, providing environments where students are allowed to search for meaning, appreciate uncertainty, and inquire responsibly.

Emergent Curriculum

Continuing with the idea of best practices brings us to a brief look at emergent curriculum. In its own way, early childhood education is constructivist in nature and so very appropriate. Emergent curriculum is curriculum that is co-constructed between children and teachers, based on the students' interests and passions. It is a nonlinear task, and can be messy in operation with no prescribed end point, all which allows children to enter and pursue the curriculum as they wish. The process requires a great deal of flexibility and creativity on the part of the teacher, as well as giving up a certain sense of control on where things will lead. Goals for emergent curriculum include addressing and respecting individual children's interests, keeping the focus on where the learner's interests lead, which may be nonspecific and without predetermined end points. This outcome is often the complete opposite of curriculum goals prescribed by teachers or school boards. Emergent curriculum is based on the premise that children are capable navigators of what they want to learn, and as Carolyn Edwards notes, "Teachers honestly do not know where a group will end up" (Edwards, Gandini, & Forman, 1993, p. 159).

Rather than an "anything goes" approach to learning, constructivist teachers can and should

help steer the process of learning. An example from this author's experience revolves around a prekindergarten class's interest in stories. While exploring stories and the various ways they can be expressed, students read multiple books by a favorite author and took a trip to a children's theater to see the story presented as a play, and this led to the group's desire to write its own book. This curriculum project emerged from students' strong interest in and early abilities to read and write. Not initially viewed as a long-term project by the teaching team, at the end of a 3-month period the students wrote, illustrated, and created a book about their classroom pet rabbit. Different areas of interest were included and investigated as they arose from the students who had a long history with the rabbit.

A writing center, art center, and classroom library were constants in the classroom, as were regular trips to the local library to check out books. In the dramatic play area, children spontaneously acted out stories from books read as well as doing reenactments of the theater production. The group even investigated how books are put together with a children's book illustrator and came to understand the multiple processes used by writers and illustrators. Children entered and exited the process as their interests guided them and in the end all children participated in and had ownership of the process and final product of the classroom book.

Cultural Competence

The issue of cultural competence and its importance in early childhood teacher education programs cannot be overstated. The term *cultural competence* reflects two ideas: *competence* being the ability to do something successfully, while *culture* can be described as the customs and social behaviors of a society. Placed together, cultural competence can be understood as the ability to successfully interact with the various customs and social behaviors of a society. As our world population continues to become more and more diverse, recognizing the inherent worth of all its members is vital. For early childhood educators, one goal of

cultural competence is that we become more aware of and more respectful of multiple cultures and customs. As such we must "look closely at our views, feelings, information, and behaviors in relation to the many issues of race, racial identity, and racism" (Derman-Sparks & Ramsey, 2011, p. 19). One of the most important aspects for early childhood teacher education is to learn about and be comfortable among the various cultures that make up the children and families served.

For preservice early childhood teachers, addressing issues around diversity is one of the most intimidating aspects of their education, according to some researchers. Asking young people to be culturally competent often raises anxiety—especially for those with limited life experience. Students typically have two main concerns. They ask, "How can we know everything about every different culture we may deal with?" And they often have the belief that "all of the children we work with are the same." Both concerns are misguided—first as educators with cultures and histories of their own, teachers do not need to know or be expected to know everything about all other cultures. Teachers do, however, need to recognize and respect differences and be aware of biases toward lifestyles or behaviors that they do not know about or understand. This includes lifestyle choices, skin color, behaviors, languages, and religious beliefs, to name a few. Second, no matter how similar teachers may think others are—their peers, the children in their care, or their families—they all have their own perspectives, beliefs, and understandings of what is viewed as normal. Understanding and working toward letting go of these issues are important steps in gaining cultural competence. As educators, "We must also help children develop individual and group identities that recognize and resist the false notions of racial superiority and racial entitlement" (Derman-Sparks & Ramsey, 2011, p. 3).

What If All the Kids Are White?, by Louise Derman-Sparks and Patricia G. Ramsey, helps clarify what is required of early childhood educators on the issue of cultural competence. Society wants educators, families, and children to embrace diversity—but it is also important that

teachers develop their own awareness about their relationships, feelings, and behaviors in dealing with issues of diversity, including race, racial identity, and racism. Doing any anti-racism work begins first and foremost with the individual self—through self-reflection and looking honestly at our own biases and prejudices. As stated earlier, teachers need to become constructivists in order to use it well. Similarly, to develop and use anti-bias multicultural curriculum, educators must accept that they all need to take the “anti-racism journey.” This is another area where the work of reflective practice can be a powerful tool for early childhood caregivers and educators. When teachers expand and deepen their awareness and knowledge of the self, “pursuing [the] work with honesty, persistence, and humility,” they not only move themselves along the anti-racism multicultural road but also provide models for others to follow (Derman-Sparks & Ramsey, 2011, p. 20).

Another way to look at working toward cultural competence is to ask the question, “What are children learning?” when an anti-bias multicultural curriculum is being used and when it is not. The saying “Children are always learning something” is a reminder that whether information is given intentionally or unintentionally, it is still given. Teachers must be aware of the messages children pick up from their teachers, families, and the wider society, including implicit and explicit messages of racial superiority and entitlement. There is a better chance that negative images of the self and others will be noticed and changed if educators help everyone recognize how these ideas are spread.

The following anti-bias education goals help illustrate how children and adults can learn to build diverse communities and societies. Depending on the background, ages, and life experiences in a group of children, each child will:

1. Demonstrate self-awareness, confidence, family pride, and positive social identities;
2. Express comfort and joy with human diversity; accurate language for human differences; and deep, caring human connections;
3. Increasingly recognize unfairness, have language to describe unfairness, and understand that unfairness hurts;
4. Demonstrate empowerment and the skills to act, with others or alone, against prejudice and/or discriminatory actions. (Derman-Sparks & Ramsey, 2011, p. 15)

Anti-bias multicultural curriculum education means holding the “hopeful possibilities and meeting challenges” (Derman-Sparks & Ramsey, 2011, p. 27) of living in a culturally competent world. In many ways, this hope is no different from what some of us expect all education to be—something that requires us to engage in our own ongoing growth and understanding about development, and learning about diversity and equity issues.

Application of Family Systems, Collaboration, and Transitions for Children

The final area to be addressed is the use of family systems theory and the collaboration and transitions that are used in various systems for children. What defines family continues to change and broaden in our society, making it imperative that early childhood education and care providers recognize that the children educators serve live within larger family dynamics or family systems. The significance of young children’s families on their development is important to any discussion of early childhood education teacher preparation. An inclusive definition of family includes people living together who care for and support one another. Multiple configurations of people with various ties and commitments to each other (blood, legal, and religious) create modern families.

Parent make-up can involve same-sex, cohabiting, divorced, and remarried couples, or single individuals. Of course, not all members of one’s family will live in the same household; home environments can include parents and one or more children, but may also include relatives of parents/children (grandparents, aunts, uncles, cousins). It is important to note that when early childhood

education programs provide services to a child those interactions and services will in some fashion include other family members. Looking at families from a systems perspective allows educators and service providers to acknowledge and appreciate that the family may follow varying patterns of behavior. This information is important to how services are determined, presented, and received.

There are several aspects to how a family's make-up can affect how the particular family system will act. Family systems theory stems from the work of Murray Bowen, who suggests we cannot understand individuals in isolation from other members of their family. The family unit is a system in which members are interconnected with and interdependent on each other. Additional theoretical approaches stem from Urie Bronfenbrenner's ecological model of human development, which offers five interactive levels or systems in which a person's life occurs. Viewed as concentric circles moving out from a center ring, the model begins in an inner circle with the *microsystem*, made up of the immediate context in which a child interacts. This is followed by the *mesosystem*, involving interactions and relationships that occur between individuals and settings of the microsystem. Next is the *exosystem*, composed of the contexts indirectly influencing the child, for example, the type of neighborhood (inner city, suburban) or the expectations of a parent's job. The exosystem exerts its influence by way of its impact on individuals and institutions in the child's microsystem. The *macrosystem* is composed of political systems, social policy, culture, economic trends, and so forth, and determines the resources, opportunities, and constraints present in the lives of children and families. Completing the model is the *chronosystem*, which interacts with all other aspects of the model representing the elements of time in the individual's life trajectory (infancy, childhood, etc.) and the historical context in which he lives (Weiss, Kreider, Lopez, & Chatman-Nelson, 2010).

In the context of this discussion on early childhood education, the idea of a child living within and affected by a system is an important one. As a child

moves from the care of her immediate family, additional important caregivers and teachers begin a collaboration of relationships and transitions. These relationships will vary due to family needs and desires, and what types of care settings are available, including nannies, early childhood program teachers, and public and private schools including kindergarten through third grade. Care and education settings may vary and include one or more of the following: center- or home-based child care, nursery school, preschool, Head Start, and before- and after-school care. Each of these transitions creates the joining of one or more systems that will overlap, coordinate with, and affect each other. Morgan (2011) notes that this environmental transition brings up sets of human needs often unrequired before. Children move from the protective environment of home (parents, special privileges) into environments of strangers where they are all—children and parents—expected to conform to behaviors that can be difficult to acquire, for example, separating from parents while at child care, competition for caregiver attention, turn-taking rules, and sharing materials. It is also crucial to mention the difficulty of these expectations and changes for those children who do not come from protective home environments—adopted children, those in foster care, or those living in residential living environments.

Looking at children and families through the lenses of systems theory and the multiple collaborations and transitions for their early care/education highlights the importance of social policy. It also raises the significance of proposed policy effects. For example, having a national program providing subsidized child care for parents in the United States would make significant changes in the lives of families with young children. This would also represent a national acknowledgment of the importance of early childhood education by our society. By recognizing the various systems in which we all live, it is easier to understand how systems might affect a child's development and early learning. It is difficult to ignore the multiple effects—social, economic, culture, and history—in which the child is born and raised when viewed within the contexts of Bronfenbrenner's system.

Adding to Bronfenbrenner's model of family systems, we can include the ecology of family engagement. Both models occur across and within contexts that include home, school, and wider communities. These different contexts are made up from various systems influencing a child's development—both directly and indirectly. Key to both models is the interconnections and influences on other systems.

Similar to understanding certain traits of family systems, there is guidance around developing and maintaining family engagement, or the connections needed as a family system moves into collaboration and transition modes. The Harvard Family Research Project (HFRP) offers the following components in its framework for building family engagement (FE) in schools and communities:

- FE occurs as a result of shared responsibility and co-construction;
- FE matters from birth to adulthood but varies over time;
- FE occurs across contexts, in both homes and schools, but in other settings as well (afterschool programs, community centers, libraries). (Weiss et al., 2010, p. xx)

Family engagement with a child's education includes helping with homework, being an advocate for one's child, and helping the child navigate different school systems. Family engagement also includes the beliefs, attitudes, and activities that families hold in order to support their children's learning, a reflection of the significant roles families play in a child's educational life, according to Weiss and colleagues. When children perceive that their schooling is important to their parents they are motivated to do well. Engagement between home and school needs to be continuous throughout the child's education, adjusting to a child's and family's changing roles over time.

How are educators prepared to engage with families? Teachers need to know how to "think critically, quickly, creatively, and responsibly" (HFRP, 2003, in Weiss et al., 2010). These skills are best learned through practicing self-reflection and real-time problem solving in supported preservice

field settings. It is important for early childhood education students to recognize that while schools and parents both want children to be successful there may be disagreement on how to achieve this. One way to approach these differences is by being able to reflect on situations from various viewpoints, those of parents, children, and self. This ability, along with respecting and valuing others (cultural competence), can help educators understand a child's needs from multiple perspectives.

Discussion

This entry began with a brief overview of early childhood education pioneers—men and women looking at and considering the period from birth through 8 years of age for children for hundreds of years. That history, together with more modern theories of development, learning, and relationships, leads educators to an important place in the field of early childhood education. So much is known about how children develop, what best practices are for children, and the specific needs of certain populations. Much of the history and research in this field inform educators: what they need to know in order to provide high-quality care, services, and education to young children. Educators have numerous choices of curriculum at their disposal, including emergent curriculum, discussed here. Looking at individual development within the wider contexts in which we live allows educators to better understand the range of care, advocacy, and educational environments children need. Coming to understand the family as a system helps educators see that they also develop within systems, helping them see the broader perspectives needed in their work. The metaphor of living and working in multiple systems is both practical and useful, especially as educators work toward consensus with families. Educators strive for social equality. Preparing children to be active participants in the world requires that educators see the inherent value in each other. This takes significant and continued commitment as educators reflect on their own practice and act as models for the children in their care.

There is an ongoing need for early childhood educators to continue to work toward learning “how children learn” and to allow children the privilege of self-direction, concrete experiences, collaborative discourse, and reflection.

EARLY HEAD START

Early Head Start (EHS) is a national program that addresses the needs of low-income pregnant women and families with children under the age of 3. EHS was authorized as part of the Head

Start Act of 1994. Since its beginning, EHS has established a legacy of providing comprehensive child development and family support services to infants, toddlers, and their families. Rigorous research has shown that EHS has positive impacts on children’s cognitive, language, and social-emotional development and improves family self-sufficiency and parental support of the children’s development. This entry describes the EHS program, summarizes findings from its national longitudinal impact evaluation, and concludes with information about the status of the program today. It is important to note that the program effects reported here come from a program that was newly funded and widely implemented across the country—not from a demonstration program or a small-scale, single-site setting.

The Early Head Start Program and Its Evaluation, 1995–2010

The New Initiative Developed and Expanded

In 1994, the Advisory Committee on Services for Families with Infants and Toddlers, appointed by the secretary of the U.S. Department of Health and Human Services (HHS), recommended a new Head Start initiative. EHS was to be a two-generation program aimed at enhancing children’s health and development, strengthening families and community partnerships, and supporting staff to deliver services to low-income families with pregnant women, infants, or toddlers. The program has grown from 68 locations in 1995 to become the largest program of its kind, with 1,020 programs in 2013 serving 111,096 children under 3 and 6,307 pregnant women. Still, 2013 funding levels enabled EHS to reach only 4% of eligible children.

EHS serves highly diverse families. At the time the national evaluation began (1996), about one-third were African American, one-quarter Hispanic/Latino, two-fifths White, and the rest Asian and other racial/ethnic groups. Between 15% and 20% of parents spoke a language other than English (mainly Spanish) as their primary language. Almost half were single-parent families, one-fifth of parents

were in school or job training, and about half were unemployed.

EHS services were provided through several different approaches. As with Head Start, EHS offered children and families comprehensive child development services through center-based, home-based (home visiting), and mixed (center and home) program options. Within these approaches, each program was encouraged to select its own specific curriculum, or to develop its own.

Mathematica Policy Research Evaluation

At the same time as the program launched, the Administration for Children and Families (ACF) in HHS funded Mathematica Policy Research and its partner, the National Center for Children and Families at Columbia University, to conduct an EHS National Research and Evaluation Project (EHSREP) along with 15 university research teams located near the participating program sites. The evaluation's purposes were to learn what impacts this new initiative would have on participating children and families, how program implementation evolved over time, and what might be learned for improving future programs.

In 1996, ACF purposefully selected 17 sites for the evaluation so that, overall, their characteristics would mirror the program approaches and diverse family characteristics of all 143 programs funded at that time. ACF required a randomized trial within each participating program. Thus, when programs began enrolling families, they recruited twice as many as they were funded to serve. Then the evaluators randomly selected about half of the 3,001 families recruited across the sites to be enrolled in the program while the other half became the control group; control group families were allowed to access any services available in the community except EHS.

This entry reports results from assessments of children and their parents completed at four time points: twice during the program period when children were 2 and 3 years old; two years after the program, when children were about to enter kindergarten at age 5; and when the sample reached fifth grade, at about age 10. At ages 2, 3, and 5,

assessments captured the full range of developmental domains (social-emotional, cognitive, health, approaches to learning, language, academic skills); parenting and the home environment; family well-being and mental health; parent self-sufficiency; and program environment. At fifth grade, age-appropriate versions of these domains were assessed, as was the school context.

A comprehensive implementation study confirmed that all programs implemented key features of the Head Start Program Performance Standards, but some did so early, some later, and some did not achieve full implementation during the study. This variation in program quality enabled the evaluation to study what difference it made. In addition, the diversity of enrolled families enabled a study of how EHS might affect different kinds of families in different ways.

Impacts of Participation on Children and Parents at Ages 2, 3, and 5

During the period of the EHS intervention, analysis of assessments at ages 2 and 3 showed a breadth of child impacts across key developmental domains. These included enhanced cognitive and language skills, reduced aggressive behaviors, higher engagement with parents during a play situation, and higher reported immunization rates. Parents also benefited from the program, with impacts on their supports for child learning, daily reading, discipline practices, and enrollment in education or job training. Some impacts were still present two years later, at age 5, when EHS significantly reduced behavior problems and enhanced positive social skills and approaches to learning. At age 5 no impacts on school-related achievement measures were found, nor were there impacts on parent-child play interactions. However, program mothers had lower depression scores when children were 5.

Analyses aimed at understanding factors that mediated program impacts helped to explain the mechanisms by which EHS may have been exerting its beneficial effects. As developmental theory would suggest, several age 5 impacts were more likely when earlier impacts had been present. For example, impacts on positive approaches

to learning at age 5 were mediated by earlier enhancements of parent support for language and literacy, child vocabulary, and reduced aggressive behavior.

Impacts on Subgroups of Families and Programs

All subgroups experienced positive impacts, but they varied. Among family subgroups, African Americans were found to experience the greatest benefits from EHS at both ages 3 and 5. Vocabulary at age 5 was better among Spanish-speaking Hispanic/Latino children (but not among English speakers). Analysis of families differing in number of risk factors (like being a teen mother or high school dropout) found that the moderate-risk group experienced the greatest number of positive impacts relative to its control group.

Among the three types of programs, those adopting the home-based approach generally, across the three ages, were most effective in improving parenting and home environment outcomes along with parental self-sufficiency. In addition, positive impacts for children's social-emotional development emerged at age 5 for those who had been in home-based programs. Mixed-approach programs had the greatest number of impacts (and the largest impacts) on children and families at ages 2 and 3, but not at age 5. Impacts in mixed-approach programs that fully implemented the performance standards were considerably larger than overall impacts at age 3, but not later.

Nonexperimental analyses exploring the role of formal prekindergarten (pre-K) programs (including Head Start) after children left EHS found both positive and negative associations: Pre-K participation between ages 3 and 5 was associated with an increase in age 5 aggressive behaviors (unless the pre-K was Head Start), but pre-K participation may have enhanced academic readiness for kindergarten. Overall, children who were in EHS until age 3 and then in pre-K between 3 and 5 fared best on age 5 measures. But the pattern depended on the type of outcome: enhanced social-emotional and parenting outcomes were explained by EHS

participation, whereas enhanced outcomes in school achievement areas were explained by Head Start and other pre-K participation. The risk of increased aggressive behavior at age 5 that was associated with pre-K participation was less of an issue for those children who had been enrolled in EHS before pre-K.

Impacts at Time of Fifth-Grade Follow-Up

At fifth grade, no overall impacts of the program were found, but some subgroups showed positive effects. By fifth grade, EHS cut grade retention by more than half for those who had been enrolled in center-based programs. EHS participation reduced retention from 19.2% for the control group to 8.3% for the EHS program group. Positive impacts for African American students were found in social-emotional development, parent support for education, and parent mental health. Hispanic/Latino mothers had achieved higher education levels. Consistent with age 2 and age 3 findings (but not age 5), negative impacts in academics were found for children in the highest-risk group. Researchers also found that the current school context played an important role: Outcomes were more positive in schools with lower poverty levels, with a mix of racial groups, but with smaller proportions of minority students.

In seven of the EHS sites, researchers obtained data from state child welfare agencies to investigate child welfare system involvement of program and control children who had participated in the EHSREP. Dramatic positive impacts occurred after children reached school age, based on documented reports of child abuse and neglect: Children who had attended EHS were significantly less likely to experience a child welfare encounter between ages 5 and 9 than were control group children. Although EHS children had significantly more reports of neglect than did the controls, the EHS group had 29% fewer substantiated reports of physical or sexual abuse across all ages 2 to 9 (and 38% fewer total encounters between ages 5 and 9).

Continued Expansion of Early Head Start

The EHS Family and Child Experiences Survey (Baby FACES) is a longitudinal study of a nationally representative sample of 89 EHS programs. When Baby FACES began in 2009, 36% of participants were Hispanic/Latino, 26% White, 23% African American, and 15% Asian and members of other racial or ethnic groups. About 29% were teenage mothers. Since 2009, Baby FACES has studied two groups of children and families: (1) pregnant women and newborns and (2) 1-year-olds. They were followed annually until children were 3 or left the program. Data included interviews with parents, staff (teachers and home visitors), and program directors; staff-child reports; direct child assessments at ages 2 and 3; video-recorded parent-child interactions; observations of classroom and home visit quality; and weekly staff reports on services that families were offered and received.

Baby FACES was designed to descriptively update and expand information collected in the EHSREP. It provided updated information on how children develop over time, particularly in language and social-emotional domains, how parents interact with their children, and the quality of services. It also captured the amount of services programs offered to families and how much of those services families received. It examined how experiences in the program, such as the quality and amount of services, were associated with child outcomes.

Key findings from Baby FACES include the following:

- Although children continued to lag behind national norms in language development, they showed improvement over time. At age 3, children scored near national norms on a measure of auditory comprehension.
- Average center and home visit quality was in the mid-range.
- Programs offered families services at recommended frequencies and the rate of service use by families was high. Families in the home-based option participated in 75% of offered visits and those in centers attended about 85% of available center days.
- Findings relating participation and quality to outcomes were mixed. For center-based families, higher quality was associated with better receptive vocabulary at age 3, and attending more center days had positive associations with auditory comprehension at age 3. No associations were found between home visit quality or amount of visits and child outcomes.

Baby FACES was not designed to answer questions about whether EHS *causes* better outcomes; the EHSREP had already shown that it can. Baby FACES, however, provides a wealth of information for program improvement efforts. It has demonstrated that programs provide the amount of services that are expected, they do so with decent quality, and families choose to participate in most of them. These facts suggest that EHS programs have the potential to continue providing a positive influence for infants, toddlers, and parents in low-income families.

EARLY INTERVENTION

Early intervention, or EI, is a relatively new field within the broader early childhood education profession. Established by the United States Congress in 1986, EI focuses on addressing the unique needs of families of infants and toddlers with or at risk for disabilities, birth to age 2 years. EI programs and services are built on principles and practices that are evidence based from across multiple disciplines, including special education, speech and language, and physical therapy. EI practices are defined by family-centered, routines-based, and multidisciplinary approaches that are unique and adaptable to the changing needs of families and young children.

Over the last few decades, the number of families and their children who receive EI services in home- and community-based settings has increased. As society moves further away from segregated placements and services for individuals with disabilities, more young children with, or at risk for, disabilities have been able to attend a variety of early childhood programs alongside their peers without disabilities. This new reality creates a compelling argument for researchers, practitioners, professional development providers, and policy makers who work within early childhood education to gain a deeper understanding of EI in order for them to effectively promote and advocate for the acceptance and meaningful inclusion of infants

and toddlers with and without disabilities and their families.

What Is Early Intervention?

Federal Statutes That Define Early Intervention

The United States Congress established free and appropriate educational programs and services for individuals with disabilities through Public Law 94-142, or the Education for All Handicapped Act (EHA) of 1975. In 1986, EHA was amended to extend services beginning at birth for individuals with disabilities through the Education for All Handicapped Act Amendments of 1986, or Public Law 99-457. This law established programs of early intervention to increase and enhance developmental outcomes and ultimately the academic success of infants and toddlers with, or at risk for, disabilities beginning at birth. It is important to note that state participation in Part C is discretionary; according to the U.S. Department of Education, as of 2014 all states and territories had opted to access federal funding through this law.

If states receive federal funding through Part C, they are mandated to establish a coordinated, comprehensive, and multidisciplinary system across key agencies to ensure that eligible infants and toddlers with or at risk for disabilities and their families have access to EI services. These services must meet the developmental needs of young children, including cognitive, physical, social, communication, and adaptive. Part H of the EHA Amendments was reauthorized as Part C of the Individuals with Disabilities Education Act (IDEA) of 1990, or Public Law 101-476, and was amended with the passing of the Individuals with Disabilities Education Improvement Act (IDEA) of 2004, or Public Law 108-446.

Eligibility for Early Intervention Services

Under Part C of IDEA, EI services are administered through individual states that require each one to create a process to identify, coordinate, and deliver services to infants and toddlers through age 2 years and their families, based on predetermined

factors. These factors include the presence of (a) an identified developmental delay; (b) a medical diagnosis known to impact development including, but not limited to, blindness, deafness, Down syndrome, or cerebral palsy; or (c) environmental risk factors such as having a parent with a diagnosed mental health disorder, being homeless, or having experienced abuse or neglect.

While every state must provide EI services to eligible infants and toddlers, each state has the discretion to determine eligibility criteria, such as the percentage of delay a child must demonstrate on standardized assessments to receive services, and whether or not to consider specific risk factors when determining eligibility. For example, while Illinois requires a child to demonstrate a 30% delay to access EI services, Tennessee requires a 40% delay, and Arizona requires a 50% delay. Interestingly, the U.S. Department of Defense requires the children of military service members to demonstrate only a 25% delay to access EI services regardless of the families' primary residence. Notwithstanding the individual state's criteria, all potentially eligible children must participate in evaluations addressing developmental needs in order to determine their eligibility for EI services. According to the 36th Annual Report to Congress (2014) by the Office of Special Education Programs (OSEP) of the U.S. Department of Education, in 2012, a total of 333,982 infants and toddlers received Part C early intervention services.

Early Intervention Settings, Service Types, and Professionals

EI services typically occur in the home, although they may be delivered in a variety of settings including but not limited to child care or center-based programs, therapy clinics, libraries, and other community-based settings. In 2012, according to the U.S. Department of Education, 87% of infants and toddlers eligible for EI services were served primarily in their home.

The types of EI services delivered are based on the specific needs of individual children and their families. According to federal regulations, EI services may include special instruction, family

education and home visits, speech-language pathology and audiology services, occupational therapy, physical therapy, psychological services, service coordination, medical diagnostic services, and screenings and assessments necessary to enable infants or toddlers to benefit from other EI services, social work, vision services, assistive technology devices and services, and transportation. Data from the National Early Intervention Longitudinal Study (NEILS) suggest that the EI services most frequently received by eligible children and families are service coordination, speech and language therapy, and special instruction for the child.

EI professionals include early childhood and special educators, physical therapists, occupational therapists, speech-language pathologists, audiologists, social workers, psychologists, registered dietitians, family therapists, vision specialists, orientation and mobility specialists, physicians, and nurses. Kathleen Hebbeler and her colleagues (2007) reported that EI professionals tend to be mostly female (95%), White, monolingual, with diverse educational experiences, and varying years of experience working with infants and toddlers with, or at risk for, disabilities. Individual states have latitude in how they ensure that EI providers have the necessary qualifications to work within their state's Part C system as national standard licensing for EI providers do not exist, nor is there reciprocity across states as each state determines its own credentialing, certification, or licensure process to demonstrate EI providers' experience and qualifications.

Foundations of Early Intervention

Early intervention draws from research conducted across disciplines including the medical, educational, behavioral, and social science fields. It is built on the growing knowledge of how infants and toddlers develop, and the nature and effects of the transactional relationship they have with adult caregivers, peers, and the environment.

Studies on brain development have greatly impacted the philosophy and approach that guide EI services. The scientific evidence on the profound impact of the environment on the development of

the human brain is compelling. Specifically, researchers point to the powerful influence of early interactions on young children's brain development. These findings highlight the vital role that families and caregivers play in facilitating children's learning and development, especially the need for consistent and responsive care by significant adults. Moreover, the National Scientific Council on the Developing Child (2007) clearly points to the importance of the early years, particularly between birth and 3 years, as a critical time for the developing brain. These findings further support the impact that quality care and intervention can have on all infants and toddlers, regardless of ability level.

Key Outcomes of Early Intervention

Many of the studies that have been conducted related to EI systems, services, and programs have documented the positive impact of EI on the well-being of infants and toddlers and their families. The Early Childhood Technical Assistance Center reported in 2014 that several intervention programs that have been implemented during the early years have produced important outcomes, such as children developing or acquiring new skills at increased rates. While over 60% of children who exit Part C services at 3 years old continue to qualify for Part B services, the NEILS data show that 32% of children who received EI services no longer qualified for special education services by kindergarten.

Furthermore, Don Bailey and his colleagues (2004) reported that important collaborations among professionals and families are linked to families' enhanced ability to meet their children's needs throughout their lives. Finally, several researchers, such as Steve Barnett (2000) and Don Bailey and colleagues (2005), have described the impact of EI on the broader economy through the decreased need for intensive supports, such as special education services as the child gets older.

Cross-disciplinary research studies also have documented the benefits of early intervention services for infants and toddlers with, or at risk for, disabilities. Discipline-specific studies have

documented the positive impact of a variety of interventions implemented with infants and toddlers diagnosed with a variety of disabilities. For example, Juliann Woods and Amy Wetherby (2003) reported how speech-related interventions have been shown to enhance children's overall communication development. Additionally, Gerald Mahoney and Bridgette Wiggers (2007) found that preparation of social workers can enhance professionals' relationships with families of children with disabilities.

Evidence-Based EI Principles and Practices

The design and implementation of EI services are guided by principles and practices espoused by the federal government through OSEP and various professional organizations, primarily the Division for Early Childhood (DEC) of the Council for Exceptional Children. OSEP's EI principles developed in 2008 focus on seven key concepts designed to provide the field with guidance when working with infants and toddlers and their families. The workgroup that developed these principles identified specific practices related to each principle. These principles have been adopted and adapted by several states, including Virginia and Illinois, to guide the implementation of EI services.

Families and children in EI are served by professionals from a variety of disciplines. Professional organizations such as the American Occupational Therapy Association and the American Speech, Hearing and Language Association offer guidance for delivering EI services specific to their professional discipline.

While there are common themes across the practices from different disciplines, only DEC provides guidance for all professionals who serve infants, toddlers, and preschoolers with disabilities and their families. While DEC's recommended practices target the broad early childhood age spectrum from birth to 5 years old, many practices are applicable to infants and toddlers with or at risk for disabilities and their families. DEC provides guidance to EI programs, professionals, and family members through a list of recommended practices organized by topic areas, including assessment, environment,

family, instruction, interaction, leadership, teaming and collaboration, and transition.

Critical Features of Early Intervention

Several key features set EI services apart from other early childhood services and programs. It is the combination of these critical features that distinguishes EI programs and services for infants and toddlers with or at risk for disabilities and their families from other early childhood services or services for older children.

Family-Centered Practices

The concept of family-centered practices is based on the belief that the family is in the optimal position to support children's developmental needs and the acquisition of new skills, partly because they spend the most time with their children, but also because they have a vested interest in their children's well-being. Family-centered practices enable families to recognize the positive impact they can have on their children and families as a whole. Bonnie Keilty (2010) wrote that research findings document the relationship between families that are functioning in a positive manner and children's growth and developmental progress. According to Don Bailey and his colleagues (2012), family-centered practices include recognizing and utilizing strengths that the family has, providing the family with the opportunity to make informed decisions based on their priorities and concerns, engaging in open and honest communication with the family, being flexible to change services depending on the child's and family's needs, and incorporating a family support system (i.e., extended family and friends) to the extent possible.

Individualized Family Service Plan

The federal law mandates the development of individualized support plans for children and youth with disabilities. For students with disabilities (3 to 21 years old), an individualized education program (IEP) sets the plan to address the individual student's needs, often focusing on educational outcomes. For infants and toddlers, the individualized family

service plan (IFSP) is developed to address supports for both the child and family; it focuses on functional outcomes (e.g., Lin will self-feed during meal times with her family). IFSPs are developed within 45 days of a child's referral to EI services. The family and EI providers meet to discuss the child's strengths and needs, goals the family has for their child, and services that would best meet those needs. While IFSPs may look different from state to state, there are key components that must be included on the plan, including (a) present levels of development; (b) family information including resources, priorities, and concerns; (c) measurable outcomes; (d) EI services that will be provided; (e) the environment in which services will occur; (f) who will be responsible for paying for services; and (g) the plan for transitioning the child from EI to an appropriate educational-based setting on his or her third birthday.

Routines-Based Interventions in the Natural Environments

Another critical feature of EI services is the emphasis on serving the child in his or her natural environment. IDEA defines natural environments as any setting that a child without a disability might routinely participate in or access. Notably, IDEA defines natural environments as home or community-based settings and, therefore, the large majority of eligible children in 2012 received services in the natural environment. However, Lydia Moore and colleagues (2012) stress that natural environments should not be perceived only as a place, but rather as a manner in which services are implemented. Thinking about natural environments in this light further supports the idea of embedding intervention strategies within a family's daily routines. It is not *where* EI services are implemented but rather *how* they are implemented.

A way of ensuring that a family is provided with the necessary tools to support their child's development is to base all interventions around a family's typical daily routines. Although a child may receive one or more hours per week of direct services, it will be up to the family to embed intervention strategies the rest of the time (e.g., work on

communication skills during meal time, dressing, and play time). As Robin McWilliam and colleagues (2009) noted, IFSP outcomes are written to address functional skills; embedding strategies into daily routines where a child will have multiple times a day to practice them has been found to result in positive developmental outcomes.

Transitions

EI services also include planning for the child's transition from EI to the local educational agency (LEA) on his or her third birthday. In 2012, according to the U.S. Department of Education, 66% of children enrolled in EI services were found to be eligible for Part B preschool services. The time surrounding a child's transition can be very overwhelming for the family, therefore structures should be in place to support the family during this time. Examples might include transition support groups, an open house where families visit the "new" school and meet the staff, and classroom visits prior to the child's third birthday. The transition process often begins between 4 and 6 months prior to a child's third birthday in order to ensure that the receiving agency has the most current reports with which to determine eligibility and develop an individualized plan.

Multidisciplinary Collaborations

Within a family-centered model where the family is viewed as the expert on their child, it follows that all members of the IFSP team work together in a collaborative manner to help the family address concerns regarding their child's development. This collaboration requires EI providers to view their role as that of a "coach" or "mentor" versus that of "expert" on what the child and family needs. According to Clare James and Gill Chard (2010), family-centered model also means that the parent role shifts from being viewed as a passive participant to being seen as the agent of change for the child.

While it is important for collaboration to occur between the family and the various EI providers supporting them, it is equally important for

collaboration to occur between the different community-based systems that provide services for infants and toddlers, including medical, mental health, and educational services. Research by Richard Adams and colleagues (2013) has shown that when these systems work together to meet the various needs of families, children demonstrate more positive outcomes in both educational and community-based settings.

Challenges and Future Directions

Mary Beth Bruder (2010) noted that while the field of early intervention has evolved over the last 25 years, it continues to face many challenges that threaten its existence. From the very beginning through today, the Individuals with Disabilities Education Act continues to be underfunded based on federal formula. In fact, the most recent data on federal appropriations reported by Alex Lazara and his colleagues (2014) show a decreasing trend in the last 10 years for Part C/EI services. Despite the increasing numbers of families of infants and toddlers with or at risk for disabilities, who are eligible for EI services, economic and sociopolitical challenges have driven many states to take steps that mean they provide fewer EI services, therefore addressing budget concerns. For example, many states are restricting their criteria for eligibility in an effort to decrease the number of children and families accessing EI services. Additionally, several states are beginning to charge fees for EI services, which impacts access for families and communities with limited economic resources. EI advocates face an uphill battle as state and federal supports for birth to 3 services continue to dwindle.

Scientific advances in early intervention have resulted in the development and validation of state-of-the-art interventions that benefit infants and toddlers and their families. A challenge lies in the translation and implementation of these research findings into the daily practices of EI professionals. At the federal, state, and local levels, the question remains of how best to prepare professionals, at both the preservice and in-service levels, who can implement evidence-based practices and

adapt these practices to meet the unique needs of individual families and the children they serve. The infusion of modern technologies in EI provides promise for more effective ways to deliver EI services for children and families, and for EI professionals to access ongoing training and professional development opportunities (e.g., Communities of Practice, Bug-in-Ear Technology, and online-based training).

While it has only been 25 years since EI was first established, the concerns and issues faced by families and communities have changed dramatically. As such, EI services must adapt to meet contemporary societal issues, such as changing immigration and migration patterns, language and cultural differences, toxic stress, and infant mental health concerns. Additional research is needed to better understand how EI can extend and enhance its underlying mission to alleviate the negative impact these issues pose on the well-being and overall development of infants and toddlers with or at risk for disabilities and their families.

EARLY INTERVENTION, LEGAL BASIS FOR

In the United States, the Early Intervention Program for Infants and Toddlers with Disabilities mandated by the Individuals with Disabilities Education Act (IDEA) was established in 1986. This federal mandate requires each state to establish a state-wide, comprehensive, and coordinated system of early intervention services for infants and toddlers (birth to 36 months) who have or are at risk for developmental delays or disabilities. The purpose of these services is to promote the development of identified children and support their families in addressing their children's learning needs. The effectiveness of early intervention is supported by research on the benefits of early intervention services and on the significance of early experiences on brain development. This entry highlights relevant federal legislation, state requirements, criteria for eligibility, the individual family service plan (IFSP), and types of early intervention services.

Federal Legislation on Early Intervention

In 1986, the amendments to the Education for all Handicapped Act (EHA), Public Law (P.L.) 99-457, expanded preschool services to all 3- to 5-year-olds with disabilities and under Part H provided a 5-year period for states to establish early intervention services for infants and toddlers who have or are at risk for developmental delays or disabilities. In 1990, the reauthorization of EHA, P.L. 101-476, was renamed IDEA. In 1997, IDEA amendments under P.L. 105-17 reauthorized early intervention services under Part C of the Act.

In 2004, P.L. 108-446, the Individuals with Disabilities Education Improvement Act, reauthorized early intervention services with the following changes: (a) the “multidisciplinary” IFSP team should include the parent, service coordinator, and at least one other person from another discipline or profession; (b) a focus on evidence-based intervention practices derived from *scientifically based research*; (c) states are permitted to extend early intervention services from 36 months until a child enters kindergarten; and (d) because supports are required for a child’s transition from Part C to preschool services parents may request that the Part C service coordinator or others be invited to the initial IEP meeting. In 2011, the *Federal Register* published the final regulations for the Early Intervention Program for Infants and Toddlers with Disabilities to reflect changes made in the 2004 amendments.

State Requirements

Each state must establish a comprehensive system of early intervention services through a child find and referral system, and personnel development to promote highly qualified personnel. Each state also must establish procedural safeguards that ensure the timely administrative resolution of parent complaints, confidentiality, and rights of parents to written notice and consent, to determine whether or not they will participate in any early intervention service, and to examine records related to their child and family. The governor must designate a lead agency to administer the

early intervention program and appoint an Interagency Coordinating Council (ICC), including parents of children with disabilities as an advisory group to the lead agency.

Eligibility for Early Intervention Services

Infants and toddlers are eligible for early intervention services if they meet one of these criteria: (a) a developmental delay in one or more areas of development (cognitive, physical, communication, social/emotional, and/or adaptive); or (b) an established risk for a condition, or diagnosed condition, that has a high probability of resulting in a developmental delay (e.g., Down syndrome, cerebral palsy, autism, visual impairment, hearing loss, or multiple disabilities); or (c) a biological or environmental risk such as medical (e.g., prematurity) or home conditions (e.g., parents with disabilities) that may significantly compromise a child’s development if early intervention is not provided.

The Individual Family Service Plan

The IFSP is both a process and a document for providing and coordinating early intervention services to a young child and his or her family. The process facilitates a family’s collaboration with service providers, sharing of information among service providers from various disciplines, identification of early intervention outcomes that are valued by the family, and coordination of services from different service providers and agencies. The IFSP document must include the following:

1. The child’s current levels of physical (fine and gross motor, vision, hearing, and health), cognitive, communication, social or emotional, and adaptive (or self-help) development
2. If the family agrees, information on the family’s concerns, priorities, and resources related to promoting the child’s development
3. Measurable outcomes expected for the child (including preliteracy and language skills as appropriate), criteria for accomplishment, timelines, and procedures for measuring progress

4. Specific early intervention services based on peer-reviewed research, when possible, that will be provided and the frequency, intensity, and methods of delivering them
5. The natural environments (e.g., the home or community settings with typical peers) in which early intervention services will be provided and, if applicable, justification for services that will not be provided in the natural environment
6. The initiation dates and duration of services
7. The name of the service coordinator who is qualified to implement and coordinate the IFSP
8. Steps to be taken to support the child's and family's transition from Part C services

Early Intervention Services

Depending on their needs, young children with disabilities and their families could receive some or all of the following services:

- assistive technology
- audiology
- family training, counseling, and home visits
- health services
- medical services for diagnosis and evaluation
- nursing services
- nutritional services
- occupational therapy
- physical therapy
- psychological services
- service coordination
- sign language and cued language services
- social work services
- special instruction
- speech-language pathology
- transportation to receive early intervention services
- vision services

The variety of possible services, service providers, and agencies involved highlights the need for coordinated early intervention services that involve multiple disciplines and agencies.

EARLY LITERACY DEVELOPMENT

Early literacy refers to the natural unfolding of a child's ability to talk, listen, write, and interact with books and other sources of print, the capacities of which begin at birth and evolve throughout the early childhood years. Formerly referred to as *emergent literacy*, the term *early literacy* acknowledges that literacy development is a developmental, ongoing process, whereas emergent literacy is now viewed as implying that there is a finite point in time at which literacy begins to emerge. This entry provides information about the relationship between language development and early literacy development, a summary of current best practices in early literacy, and policy recommendations for supporting early literacy development in preschool and kindergarten.

Language and Early Literacy Development

There is a rich and comprehensive relationship between children's language development and their early literacy development. Language provides the

foundation for literacy. Right from birth, infants use facial expressions, sounds, and gestures to communicate their needs. Parents and teachers foster language development when they make frequent eye contact with babies, talk to them, engage in turn-taking conversations as babies begin to coo and babble, and when they sing and read to them. These responsive interactions—grounded in loving relationships with caregivers—stimulate babies’ understanding of how we use language to communicate. Children’s developing ability to communicate using spoken language (in both speaking and listening) simultaneously supports their early literacy development. This is particularly true with regard to providing joyful experiences with books, stories, songs, drawing, and scribble writing.

As infants grow into toddlers, their vocabulary burgeons tremendously. They come to *understand* more and more words while they also begin to communicate their thoughts and desires *verbally*. Parents and caregivers continue to promote language and early literacy development when they actively respond to toddlers. When toddlers begin communicating with words, caring adults extend these verbal approximations. For example, Gabriel says, “Eek-oo,” in a sing-song voice. The parent responds, “Where’s Gabriel? Peek-a-boo! I see you! You were hiding behind the bean bag.”

As children move into the preschool and kindergarten years, their ability to engage with print as listeners and as early readers and writers increases. This growth is highly influenced by the responsive interactions they experience from birth to age 3.

Best Practices in Early Literacy

There are innumerable experiences that parents and teachers can provide to foster children’s early literacy development. The following is a list of some of the most powerful experiences, organized by category and listed in order of developmental stage:

Language Experiences

Copy baby’s sounds and listen to see what sounds he or she makes in response

Narrate routine experiences, such as diapering, dressing, and bathing, describing the action as it is being performed

Name familiar objects in baby’s daily life (toes, fingers, nose, bottle, blanket, pacifier)

Listen to the child; extend the child’s language as he or she begins to talk

Play the Rhyming Game by first saying two words that rhyme and then inviting the child to tell another rhyming word

Say as many words as the adult and child can think of that start with the same sound (toy, tiger, top, tree, Tara, toe)

Reading Experiences

Read together every day

Provide a variety of durable board books for babies to mouth, hold, and practice page-turning

Point out details in illustrations, use different voices

Reread favorite books and invite the child to “read” pages or familiar parts

Print Experiences

Give the child chubby crayons or markers and paper; encourage the child to make marks on paper
Play with chalk

Put photos of family, friends, or favorite items in an album and label each picture; read the picture book

Have the child tell about his or her picture and write down what he or she says; read it together

Read familiar signs while walking or driving, and read print on familiar objects in the home (McDonald’s, STOP, Cheerios)

Have the child write his or her own grocery list at the same time as the parent

Play Experiences

Put foam letters in the bathtub to explore

Play with materials that build small muscle strength and fine motor skills, such as playdough, stringing beads, and finger paints

Play with stuffed animals, dolls, action figures, or puppets to make up or retell stories

Gather props to play out a familiar story

Policy Recommendations

Policy recommendations related to early language and literacy development focus on a number of key issues related to children's future success as readers and writers. All children should have access to early childhood programming with developmentally appropriate literacy components. This includes well-prepared teachers who know how to meet children where they are and provide relationship-based experiences to promote language and literacy development. Programming must include specific attention to meeting the needs of English language learners as well as children of diverse abilities and backgrounds.

Programming should include ways to promote family engagement. Educating families in ways to support children's early literacy development is critical so that children experience a language- and literacy-rich home environment. Funding must be dedicated to supporting early language and literacy development in infants and toddlers, as well as in preschoolers. Early literacy curricula and teaching practices must be evidence-based and integrated across all developmental domains.

EARLY NUMBER REPRESENTATION DEVELOPMENT

The focus of this entry is the development of children's sense of relative magnitude involving symbolic (verbal or written) numbers. In order to better understand young children's perspective on relative magnitude, consider the following exchange by a 5.5-year-old girl, Arianne, with her father (the author) on his 42nd birthday:

"How old are you today, Daddy?"

"Forty-two."

"Is that close to a hundred, Daddy?"

Arianne's follow-up question illustrates an important phenomenon in this development of number knowledge. For the 5.5-year-old, the difference in the magnitude of familiar numbers such as "four" and "ten" was clear—"ten" and "four" represented clearly distinct magnitudes, the former was much more than the latter, and psychologically "ten" was far apart from "four." For Arianne, though, the difference in the magnitude of unfamiliar numbers such as "forty-two" and a "hundred" was unclear. For her, "a hundred" was a big number and "forty-two" also represented "many" or "a lot" and was, thus, psychologically close to "a hundred." As children's familiarity with numbers up to 100 grows, they realize that there is a big difference being 42 and 100 years old—that, for instance, 42 is not even halfway to 100!

In order to better understand Arianne's perspective, consider the problem in Figure 1.

Figure 1 A Million, a Billion—What's the Difference?

If 0 = zero and 1B = a billion and **a** < 1/100, **b** = 1/100, **c** = 10/100, **d** = 50/100, **e** = 90/100, **f** = 99/100, and **g** > 99/100, what letter best represents the position that a million would occupy on the number line below?

Although most adults know that a billion is more than a million, they have little sense of how much bigger a billion is than a million. That is, most adults do not have a good sense of the relative size of a million and a billion. As a result, many locate a million at *d* or—close to a billion—at *e*, *f*, or even *g* on the number line. For most adults, it is surprising that the solution to the problem is choice *a*. In fact, a million is merely 1/1,000th of a billion or, put differently, a billion is 1,000 times larger than a million!

Gradual and Continual Expansion of a Sense of Relative Magnitude

The vignette of Arianne and the problem depicted in Figure 1 illustrate that an understanding of the relative magnitude of numbers develops as familiarity with larger and larger numbers grows. For many 2-year-olds, just learning the meaning of number words, “two” may initially refer simply to any plurality. For example, Alexis Palmer and Art Baroody (2011) reported that, between 23 and 25 months of age, Blake spontaneously labeled collections of more than one as “many” and, at 26 months, used “two” for the same purpose. Over the next 2 months, his precision in using “two” grew to 50% accuracy and then more than 90% accuracy—at which point other number words serve to indicate “many.” Shea, a 3-year-old in a public school preschool, could re-create a collection of one or two items that was still visible or previously shown and then hidden. However, with larger collections of three or four—both of which she labeled “three” or “a bunch”—she regularly put out four or more objects. Indeed, many children use

“two” and then “three” to indicate “many” instead of a specific quantity.

Learning the counting sequence lays the foundation for greatly expanding number sense beyond the “intuitive numbers”—the small collections that children can learn to subitize (recognize and label with an appropriate numeral without counting). By 4 years of age, Barbara Sarnecka and Susan Carey (2008) observed that children have learned that the number words in the counting sequence represent different and specific quantities of increasingly larger size—the “increasing magnitude” concept. This permits children to recognize, for example, that “nine” is more than “three” because “nine” comes (much) later in the counting sequence. In time, as their familiarity with the counting sequence grows and they learn to immediately recognize number-after relations such as nine comes after eight, they can fluently specify that “nine” is more than its immediate counting predecessor “eight.”

Conceptual Basis of an Exact Representation of Relative Magnitude: Successor Concept

Although the increasing magnitude concept is an important development and permits children to order number words or numerals by relative size, it does not necessarily guarantee that they understand how much more, for instance, “nine” is than “eight”—specifically that “nine” is exactly one more than “eight.” Véronique Izard, Pierre Pica, Elizabeth Spelke, and Stanislas Dehaene (2008) hypothesized that the *successor function* or *successor concept* is hypothesized to be one prerequisite

Figure 2 Conventional Number-to-Point-on-a-Number-Line (N-P) Task

Instructions: "If this is where 0 goes (pointing) and this is where 10 goes (pointing), where does 7 go?"

of the concept of exact natural numbers needed to operate on and compare quantities. As illustrated by Kindergarten Counting and Cardinal Goal 4c of the Common Core State Standards (Council of Chief State School Officers, 2010), this concept entails "[understanding] that each successive number name refers to a quantity that is exactly one larger" than its predecessor in the counting sequence. Theoretically, the construction of the successor concept enables children to re-represent the count sequence as an integer sequence— n , $n + 1$, $[n + 1] + 1 \dots$ (e.g., 1 , $1 + 1$ or 2 , $2 + 1$ or $3 \dots$).

The Successor Concept and Development of a Linear Representation of Number

Lauren Resnick (1983) termed children's representation of the relative magnitude of numbers—the relations among numbers of different size—a "mental number line," which involved progressively larger numbers when moving from left to right. Not coincidentally, researchers interested in how children represent relative magnitude have often used a number-line task. The "conventional" task used with preschoolers involves giving them a number such as 7 and asking them to point where it should go on a number line with end points marked with 0 and 10. This number-to-a-point-on-a-number-line (N-P) task is illustrated in Figure 2. (With older students, a 1-to-100 or a 1-to-1,000 number line is used.)

A child who views all numbers from "one" to "ten" as having the same magnitude would place all numbers at about the same position on the number line shown in Figure 2. For example, in Figure 3, Cell A illustrates the result of a child who

always pointed toward the left-hand endpoint on the number line (about 1) regardless of the number presented. Note that the graph of the results in Cell A is basically a flat horizontal line (a straight line with a slope of essentially 0) with a y -intercept of about 1. Cell B of Figure 3 represents a case where a child always pointed to roughly the middle of the number line regardless of number presented.

Cell C of Figure 3 represents the results of a child who had begun the process of representing the relative magnitudes of numbers. Specifically, the child viewed the small numbers "one" to "four" as clearly different in magnitude and placed these numbers in roughly their correct position on the number line but saw larger numbers—especially 8, 9, and 10—as less distinct and bunched these numbers together. Put differently, the estimated difference between 5 and 6 is smaller than that between 2 and 3 and the estimated difference between 8 and 9 is smaller yet. When graphed, the responses form a curved line that can be represented by a logarithmic function (see, e.g., Cell C of Figure 3).

In time, children recognize that *each successive number increases by a constant amount* (e.g., that the difference between 5 and 6 or 8 and 9 is the same as that between 2 and 3). Theoretically, a child who understands this concept but who has not yet constructed the successor concept (i.e., does not realize that the constant difference was 1) would produce results on the N-P number line task that would be linear (a straight line) with slope of more than 0 and a non-0 y -intercept, such as that shown in Cell D of Figure 3. The graphs of children who understand the successor concept would look similar, except that the slope would be 1 (each successive

Figure 3 Different Representations of Numbers (Ns) 1–10

number is one larger than its predecessor) and the y-intercept would be 1 (because 1 has an estimated magnitude of 1 unit; see Cell E of Figure 3).

Research by Ilaria Berteletti, Daniela Lucangeli, Manuela Piazza, Stanislas Dehaene, and Marco Zorzi (2010) and Robert Siegler and colleagues (2009) has found evidence of a shift from a flat representation (similar to Cell B in Figure 3) or a *logarithmic representation of number* (similar to Cell C in Figure 3) to a more linear one (similar to Cell D or even Cell E) among preschoolers, primary-grade students, or both. Moreover, in a cross-sectional study involving 4- to 6-year-olds, Erin Reid, Art Baroody, and David Purpura (2011, 2015) found that those who understood the successor concept had significantly better linear representations.

Importance of the Successor Concept and a Linear Number Representation

Constructing the successor concept and, by extension, a linear number representation is critical to developing number sense (e.g., understanding number relations and estimating relative size) and provides a solid foundation for school mathematics. For example, Julie Booth and Robert Siegler (2008) found that a more accurate representation of number is significantly associated with better understanding of operations on numbers in particular and higher levels of academic achievement in general. Conversely, David Geary, Mary Hoard, Lara Nugent, and Jennifer Byrd-Craven (2008) found that children with a mathematics learning disability, or those who have low mathematics achievement, have been found to have less accurate representations than typically achieving students. Elizabeth Gunderson, Gerardo Ramirez, Sian Beilock, and Susan Levine (2012), for example, found spatial skills, a linear representation, and approximate symbolic calculation are significantly inter-related.

Indeed, as illustrated by the learning progression in Table 3 of the 2013 National Center for Education Evaluation and Regional Assistance (NCEE) practice guide for teaching early mathematics (Frye et al., 2013, p. 13), the big idea of the

successor concept and its by-product (a linear representation) may be critical for the development of many aspects of early numeracy that form the foundation for later success in school mathematics and everyday life. Consider the following examples:

- The transformation of the counting sequence into an integer sequence may be children's first introduction to *growing number patterns*. Insight that the counting sequence embodies a constant +1 function is necessary to comprehend and recognize other, more sophisticated growing patterns such as the even numbers (+2 function starting with 2), the odd numbers or the "growing L" (
 $\begin{smallmatrix} \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \end{smallmatrix}$
) pattern (+2 function starting at 1), other skip counts such as counting by fives "5, 10, 15 . ." (constant of +5), or doubling such as 1, 2, 4, 8, 16 . . . ($\times 2$ function).
- Knowledge of the successor concept and an integer representation would seem to be developmental prerequisites for *informal mathematical induction*—making a generalization about a reoccurring pattern (recursive property) for successive integers, a conclusion that is also necessarily true of all subsequent integers. Such reasoning can lead a child to conclude, for instance, that the counting or natural numbers are unending or infinite.
- The successor concept seems essential for extending an understanding of addition beyond small numbers, and (informal mathematical) induction can be a key bridge between small numbers, which can be subitized (immediately recognized without counting and labeled with a number word), and larger numbers, which must be counted (at least in theory) to quantify. The successor concept and informal mathematical induction may enable children to use concrete experiences with adding 1 to collections of 1 to 3 (e.g., seeing that two items and *one more item* is three items), known small n number-after relations ("three" immediately follows "two" in the counting sequence), and known large n number-after relations (e.g., "eight" follows "seven") to deduce the general *number-after rule for adding 1*: the sum of any number n and one more is the number after n in the counting

sequence (e.g., recognizing that the sum of $7 + 1$ is the number after *seven* when we count: “8”). Fluency with the *number-after rule for adding 1*, in turn, serves as a scaffold for inventing advanced mental addition strategies, including the “counting-on” strategy to add and reasoning strategies that transform more difficult unknown combinations into easier, known facts. For instance, the near-doubles reasoning strategy involves solving the relatively difficult and unknown combination $5 + 4$ by logically thinking: $5 + 4$ is 1 more than (the easy) fact $4 + 4$ (because 5 is 1 more than 4); so if $4 + 4 = 8$, then $5 + 4$ must be 1 more than 8; therefore (using the known number-after rule for adding 1) $5 + 4$ is 9. Similarly, the make-ten strategy entails solving the relatively difficult unknown $7 + 9$ combination by using the knowledge of easier add-with-10 combinations: If $7 = 6 + 1$, (using the known number-after rule for adding 1) $1 + 9 = 10$, and $6 + 10 = 16$ (because any single-digit number added to 10 is the teen version of that number), then $9 + 7 = 9 + [1 + 6] = [9 + 1] + 6 = 10 + 6 = 16$). Nancy Jordan, David Kaplan, Chaitanya Ramineni, and Maria Locuniak (2009) found that mental addition, in turn, may be an important bridge between informal and formal mathematics and is predictive of later school mathematics achievement.

Early Intervention Research

The importance of a linear representation has motivated considerable recent interest in developing and evaluating interventions to promote this key aspect of number sense among preschoolers, particularly those at risk for academic failure. Such research revealed that playing linear-numbered board games with equal-size spaces that are numbered sequentially (The Great Race) significantly improved middle-class and at-risk preschoolers’ linear representation of the numbers 1 to 9 and other key aspects of early numeracy: *verbal counting* to 10, *number comparisons* (e.g., “Which is more—five cookies or four cookies?”), *numeral identification* 1 to 10, and arithmetic problem solving. For example, pretesting in Geetha Ramani and Robert Siegler’s (2008) study revealed that, on average, their participants treated the

numbers from 1 to 10 as having the same magnitude (4.5). Specifically, pretest results were linear with a nearly flat slope (similar to the graph depicted in Cell B of Figure 3 with a y-intercept of between 4 and 5). On the immediate and delayed posttests, participants who received the experimental (linear number board) training exhibited improvement (some constant differences among numbers as shown in Cell D of Figure 3), whereas participants in the control condition continued to exhibit a nearly flat slope (as shown in Cell B of Figure 3). Ramani and Siegler concluded that playing a linear board game can help children improve their representation of the counting sequence and other important aspects of number knowledge.

Making Sense of the Research

The results of existing research may not be as straightforward or clear as Ramani and Siegler’s (2008) previously stated conclusion suggest. There are at least three reasons to suspect that the conventional N-P task does not accurately measure a change in young children’s representation of the counting sequence.

1. *A number-line task may be inconsistent with children’s informal view of numbers.* Young children’s informal concept of number and representation of the counting sequence is probably based on their experience with determining the total number (cardinal value) of discrete items in a collection. That is, it is likely grounded in a discrete-quantity view of number and what Karen Fuson (1992) called a *cardinal meaning of number*. Number lines, however, represent linear extent—a continuous quantity—and, thus, embody what Fuson (1992) called a *measurement meaning of number*. Successfully indicating relative magnitude of a number on a number line would seem to require coordinating a cardinal and measurement meaning or flexibly switching between the two. A measurement meaning of number would seem to entail constructing a concept of measurement in general and a concept of linear units in particular—knowledge that typically develops later than children’s informal

understanding of numbers based on collections of discrete items. Such knowledge would enable children to devise one successful strategy for the N-P task—iteratively applying a unit of length. For example, to identify the location of 4 on a 0 to 10 number line, a child could partition the number line into 10 equal segments (units) and count off the first four. However, many children struggle to understand the process of measuring length well into elementary school. For example, in a 2010 study, Geoffrey Saxe and colleagues found that even fifth graders struggled with number line-based problems that required the application of a concept of linear unit. For example, shown a number line with 8 and 10 marked and labeled, students located 11 at the position for 12 (i.e., they incorrectly considered the distance between 8 and 10 as one unit).

2. *The conventional number-line task may tap other relatively advanced number knowledge.* Alternatively, Hilary Barth and Annie Paladino (2011) and Emily Slusser, Rachel Santiago, and Hilary Barth (2013) argued that successfully indicating relative magnitude on a number line could be achieved reasoning proportionally. For instance, to identify the location of 4 on a 0 to 10 number line, a child could reason that 4 is $4/10$ ths or $2/5$ ths—somewhat less than half of the way between 0 and 10. Regardless of strategy chosen, a conventional N-P task, which uses 0 as the left endpoint, requires children to understand a concept of zero, which—as research by Laura Bofferding (2014) indicates—develops relatively late.

3. *The conventional number-line task may be confusing to less developmentally advanced children and prompt the use of response biases.* For the reasons noted in Points 1 and 2, young children, particularly those from low-income families or otherwise at risk for mathematical learning difficulties, may be confused by the conventional N-P task. As a result, they may be unsure where on the number line to point and may resort to a response bias. As the target number is shown above the midpoint of the number line, some may seize on a “midpoint response bias”—consistently

point to the middle of the number line as their estimated magnitude, regardless of the numeral shown (actual magnitude).

Consistent with Point 1, research indicates that estimating the magnitude of discrete quantities (collections of dots or numerals) “is based on different processing strategies and follow[s] different developmental trajectories” than that of a continuous quantity such as area (Sella, Berteletti, Lucangeli, & Zorzi, 2015, p. 758). Dale Cohen and Barbara Sarnecka (2014) compared 3.5- to 8-year-olds’ performance on the conventional bounded N-P task and an unbounded version and concluded that “performance on the traditional, bounded number-line task likely reflect the growth of task-specific measurement skills, rather than changes in the child’s understanding of” the cardinal number sequence (p. 1640).

Consistent with Points 1 and 2, research further indicates that the conventional N-P task does, indeed, require knowledge of concepts and skills that go well beyond understanding that each successive cardinal number in the counting sequence is one more than its predecessor, is confusing, or otherwise underestimates knowledge of the successor concept. In a 2010 study, Berteletti and colleagues used an N-P task with the more familiar number 1 as the left endpoint. In two experiments with separate samples of 3.5- to 6.5-year-olds, children’s accuracy was better than observed in studies using the conventional task. Using a counterbalanced between and within subject design, Reid and colleagues (2015) found that 4- and 5-year-olds performed significantly better on a “user-friendly” version than on the conventional number-line task. The former task used 1 as the left endpoint and a hopping-along-a-trail analogy to relate the number line to a familiar discrete quantity situation. Moreover, children performed worse on both number-line estimation tasks than on a task that more directly gauged children’s knowledge of the successor concept.

Consistent with Point 3, a mid-point response bias might account for why Ramani and Siegler’s 2008 and 2011 pretest results and their controls’

posttest results were neither logarithmic nor linear with a slope appreciably larger than zero but a nearly flat line with an intercept of between four and five (as illustrated in Cell B of Figure 2). In contrast, an examination of the fit statistics in the 2010 study by Berteletti and colleagues indicated that their participants, who saw a comprehensible 1 to 10 number line *and* the target number in the upper left corner, were not prone to a response bias on a non-conventional task. Moreover, in Reid and colleagues' (2011) user-friendly task, which involved the tester reading a target number to a participant, 4- and 5-year-olds were less prone to mark their estimates in the middle of the number line or use a mid-point response bias on the modified version than on the conventional N-P task (7% versus 37% of response biases, respectively). In addition, in their 2015 study, Reid and colleagues found that response biases accounted for 18% of all their 4- and 5-year-old participants' responses, and the most common response bias involved marking estimates at the endpoints of the number line, primarily on the left endpoint (as shown in Cell A of Figure 2).

The impact of training that involves playing a linear board game (The Great Race) on transfer to number tasks is mixed at best for three reasons.

1. Ramani and Siegler (2008) found significant transfer to counting, numeral identification, and comparing numbers when the comparison group received non-mathematical (color) training. However, these results are ambiguous at best. Although the pretest–posttest gains for The Great Race group were significant and those for the comparison group were not, it does not statistically follow that The Great Race group outperformed the comparison because the relative gains were calculated separately. That is, such indirect comparisons are not a statistically acceptable method for determining which group is “higher.”

2. Significant results do not necessarily indicate practical significance. For example, the significant result for counting found by Ramani and Siegler (2008) is the result of The Great Race group learning about one more counting word. This small gain

was achieved with 1.33 hours of individual training, and it is unclear what component(s) actually had the impact and if other number sense training might be even more effective.

3. There has been little evidence of transfer in subsequent training experiments, including those in which the comparison training focused on number sense. Siegler and Ramani (2008 [linear track versus color control]; 2009 [linear or a circular track versus number sense control]) and Ramani and Siegler (2011 [linear or a circular track versus number sense control]) found that training with The Great Race did not produce significantly greater gains in counting and numeral identification. Only The Great Race intervention in Siegler and Ramani (2009 [linear track versus number sense control]) produced significant improvement by the linear-track group in comparing numbers.

In brief, conclusions about the impact of playing The Great Race on the linearity of young children's representation of the cardinal counting sequence and their development of cardinal number knowledge await further research.

Conclusions and Future Directions

Resnick's (1983) use of the term “mental number line” to describe preschoolers' mental representation of (cardinal) counting sequence and key numerical relations it can embody is unfortunate. As Figure 4 illustrates, what Resnick was really describing was a “mental number list”—a series of the natural or counting numbers (1, 2, 3 . . .) order by magnitude. Although similar to a number line, number lists are—as Douglas Frye and colleagues (2013) noted—developmentally more appropriate for young children, because they better fit young children's informal (cardinal) view of number.

A number of unresolved issues remain. Francesco Sella and colleagues (2015) attributed their participants' ability to estimate the relative magnitude of continuous quantities successfully on a number line to their ability to engage in proportional reasoning—which contradicts Barth and

Paladino (2011) and Slusser and colleagues' (2013) explanation for why young children fail to do so with numbers. Given the difficulty elementary children have with multiplicative reasoning—a key basis for proportional reasoning with numbers—the explanation of Sella and colleagues needs to be investigated. One possibility is that their participants used an informal and inexact form of proportional reasoning that is not based on multiplicative reasoning. Other issues that need to be explored are: What is the developmental relation between the successor concept and a linear representation of cardinal numbers? How can instruction effectively promote each? When and how do children connect a linear mapping of cardinal numbers (discrete quantities) and a linear mapping for numbers representing a measurement meaning (continuous quantities)?

ECONOMIC DIFFERENCES IN PLAY

Socioeconomic status (SES) is a topic of great interest to those who study early childhood education. With globalization and increased diversity within societies, economic and social inequalities have worsened, making poverty a leading global problem. Using data on stunted growth in early childhood and absolute poverty, a 2007 article in *The Lancet* estimated that 200 million children under 5 years old around the world are not fulfilling their full developmental potential. The ecological systems model developed by Urie Bronfenbrenner and Pamela A. Morris illustrates that the child is within the context of his or her family and community, and influenced by broader cultural systems that maintain the social values the child will internalize. This makes the lives of children from low-income families unpredictable and challenging.

There are two chief perspectives on the reasons for differences seen among children with lower

SES status and their better-off peers. The first is that these differences are a result of a lack of financial resources. Families with lower income have less access to health care, nutritious meals, enriched home environments, and high-quality child care settings. Another explanation is that these differences result from not only a lack of money, but parental characteristics that are also associated with poverty. Low-income parents tend to have less education, higher rates of single and teen parenthood, and poorer health.

The research on childhood poverty rarely considers the impact childhood poverty has on early childhood play. A few studies related to sociodramatic play have examined socioeconomic differences in children's play. Sociodramatic play, in particular, contributes to children's overall cognitive, social, creative, and language development. In seminal play research, Sara Smilansky analyzed two groups of Israeli children aged 3 to 6 from different socioeconomic backgrounds. One group was of European descent and was identified as middle class; the second group of North African parentage was categorized as lower class. Smilansky identified critical components of sociodramatic play: (a) role-playing, (b) make believe, (c) social interaction, (d) verbalization, and (e) persistence. She found that among the lower-class children there was less sociodramatic play. Smilansky proposed adults target these play components for intervention. Results similar to Smilansky were reported with children in Brazil by Yumi Gosso, Maria de Lima Salum Morais, and Emma Otta in 2007. These authors studied pretend play of different cultural and socioeconomic groups and found children from high- and middle-income groups engaged in more pretending than other groups.

Contrary to these studies, research conducted in 2006 by Sally Dyer and Giovanni Moneta did not find any social class differences in pretend play with British children 3 to 5 years of age. The authors used Mildred Parten's categories of parallel, associative, and cooperative play in low-income and high-income nursery schools. Similarly, in an earlier study in the United States, Lisa Weinberger and Prentice Starkey compared the

play behaviors of African American 4-year-olds in a Head Start setting. The play was categorized into cognitive play types of functional, constructive, and pretend play. The authors found that the children engaged in high-quality pretend play with respect to object use and number of participants involved in play scenarios.

The research is in disagreement as to whether there are economic differences in the play of children. There are several factors that account for the inconsistencies in research findings on play and social class differences. First, the research defining social class and play has not been consistently defined. Some studies use variables related to financial status (e.g., free and reduced-price lunch, family income) others use parental characteristics (e.g., education, single parenting). Another factor related to inconsistent findings may be the result of culturally insensitive research methods. It is important that play assessments are provided in the child's home language and tested by an examiner who speaks the child's native language.

Research related to play and SES needs to employ a community-level SES measurement that relates to the ecological systems approach developed by Bronfenbrenner and Morris. The neighborhood in which a child resides is associated with his or her health and level of academic readiness for kindergarten. Different neighborhoods also have different racial and ethnic compositions and levels of residential mobility. The Early Development Instrument (EDI) is a population-based measure of children's development. Lynn Cohen and Dana Friedman reported a study in 2015 using the EDI assessment to measure kindergarten readiness, but the results could be used to research pretend play in high- and low-income settings within a given community.

Regardless of whether there are differences in social play between affluent and poor children, it is important to view children's play as a resource to face adverse and challenging issues. The late Brian Sutton-Smith proposed that during play, children can experience primary emotions without losing control. Sutton-Smith considers play as dialogue for children to express and control emotions such

as anger-strategy, fear-courage, shock-resilience, disgust-imagination, loneliness-bonding, and mania-charisma. Regardless of affluence or poverty, children face challenges such as separation and loss, family tensions, violent experiences, and unsupportive environments. Play is a healing experience for children facing emotional challenges as they mediate their emotions and experience self-regulation of attention and acting-out behaviors.

On a final note, it is important that early childhood educators and researchers expand and deepen play theory to challenge, destabilize, and harness the potential of multiple perspectives of contemporary thinking about play. Developmental theories dominate the research: Most studies rely on Jean Piaget's cognitive developmental theory and Lev Vygotsky's sociocultural approach. When examining SES and play, researchers need to broaden their frameworks to include an ecological community model to better understand the complexity of poverty.

ECONOMIC STATUS AND GEOGRAPHIC INFLUENCES ON DEVELOPMENT AND LEARNING

Children actively engage the people and the objects resident in the places they inhabit. But what children do and what it means for long-term development depend on what those places afford by way of opportunities and challenges. This entry focuses on economic and geographic factors that help determine those opportunities and challenges, with particular attention to how they promote or pose risks for children's development and learning.

Young children have limited capacity to determine what their surroundings afford by way of supports for productive engagement and positive benefit. Much depends on what caregivers bring to the mix. However, what children derive from their surroundings is not solely a function of the human and social capital connected with caregivers. Bioecological theories speak to the wide diversity of conditions that have a bearing on what children experience both in and through time. Useful in this regard are two broad concepts: (1) there are both proximal (microsystem) and distal (macrosystem, mesosystem, exosystem) factors that offer opportunities or pose risks to children's development, and

(2) particular resources and risk conditions can operate through a multiplicity of interconnected processes to influence developmental course.

Household Socioeconomic Conditions

There is broad consensus that access to human, financial, and social capital connected to family socioeconomic status (SES) is important for children's development. Although there are challenges as regards how best to measure SES, there is evidence that constantly living in poverty has negative implications for health, competence, and adaptive functioning, with research showing that the effects begin prior to birth. With advances in biological assessments, it has become increasingly clear that adversities connected to low SES become biologically embedded and can even extend to subsequent generations.

Health

Poor children are more likely to experience a wide variety of health problems beginning in utero. They are more likely to be born prematurely, at low birth weight, with asphyxia, a birth defect, a disability, fetal alcohol syndrome, and AIDS. After birth, low-SES children are more likely to suffer injuries and to die, and they are more likely to manifest problems with neurobehavioral development. During childhood, SES is implicated in many diseases, including asthma and respiratory illnesses. Such problems can result from living in poor housing conditions. When homes are poorly constructed or dilapidated, children are at increased risk of disease exposure from rats, roaches, and mosquitoes. Low SES is also associated with an increased risk of dental caries, high blood lead, iron deficiency, wasting, stunting, obesity, hyperactivity, and sensory impairment. When low-SES children experience health problems, the consequences are often more severe. They are more likely to suffer health complications and to die from injuries and infections at every age. What accounts for all these health problems among low-SES children (the so-called SES-health gradient)? The studied pathways are numerous and include exposure to disease

pathogens and pollutants; living in crowded, noisy, and dangerous conditions; and inadequate nutrition and health care (including dental care).

In low-income countries, many households do not have sources of clean water or provisions for adequate sanitation, leaving young children at particularly high risk of bacterial and parasitic illnesses. Not having proper facilities to deal with waste contributes to childhood illness and mortality. Finally, some of the effects of low SES on health seem to reflect chronic stress exposure. There is mounting evidence that stress leads to damage in multiple biological systems and that stress exposure early in life may be particularly harmful. By contrast, children from high-SES families tend to get good health care, have access to nutritious foods, and live in circumstances that are less chaotic or dangerous. Consequently, high-SES children tend to be healthier.

Competence

There is also a long history of research documenting relations between household SES and the development of competence. Notable are impacts on language and cognitive processing. There is mounting evidence that growing up in a low-SES environment leads to decrements in neural development. The pathways linking SES to competence development are multiple, and they overlap those implicated in health. As an example, Vonnie McLoyd pointed to high levels of stress and inadequate parental monitoring as vehicles that help explain lower achievement for poor children; there is a deep literature on the adverse consequences for cognitive development that derive from exposure to heavy metals and other teratogens. Far and away the most studied pathways are those involving children's access to various forms of stimulation, as competence development in every domain requires adequate exposure to appropriate forms of materials and social experiences, and careful structuring of those experiences. Engagement in complex communications with others, access to books and toys that encourage exploration and learning, efforts on the part of others to teach particular concepts and skills, and access to enriching out-of-home facilities

(e.g., parks, museums) have all been explicated as means of promoting competence in children. Such experiences also appear to foster motivational tendencies that increase the likelihood children will access opportunities for learning on their own. However, the pathways can be relatively indirect as well; for example, high-SES children are more likely to attend high-quality schools and affiliate with academically competent peers.

Adaptive Behavior

The relation between low SES and maladaptive behavior is well established. Research shows that living in a low-SES home impacts physiological arousal and decreases self-regulatory competence beginning quite early in life. By contrast, high-SES families tend to be better organized and high-SES parents are more likely to engage in behaviors that lead to social competence and a high sense of agency (warmth, responsiveness, good monitoring, encouragement, problem-solving discussions). Living in adversity increases the likelihood that parents will engage in actions that foster maladaptive behavior (e.g., hostility, harsh discipline, inconsistency), and it decreases the likelihood that parents will enact behaviors that promote socioemotional competence. The patterns are consistent with arguments that living in conditions of adversity produce stress for parents, thereby reducing parents' ability to effectively engage offspring. The patterns also link to findings that show that low SES is connected with parental characteristics such as depression and low intelligence, which may contribute to the likelihood of poor adaptive functioning. In effect, some of the connection between SES and child learning and development may be genetically mediated.

Life among the poor is often more chaotic (e.g., noisier, disorganized living conditions, less stable residential and working conditions). The lack of predictability can lead to more family conflict and less family cohesion, poorer parenting, worse health, greater difficulty attending, more off-task behavior, poor school achievement, greater difficulty with self-regulation, and degradation of biological systems because of stress.

Geographic Location

Harry Heft argued that the affordances of the environment are its *functionally significant* properties, considered in relation to a particular individual. Affordances pertain to relations between features of the environment and the capacities and proclivities of humans that encounter them. The exact same physical feature or arrangement of features may provide a different set of opportunities or challenges to different children, depending on age, gender, health status, culture, personal history, or the other features present, including those with whom they interact. Through time these phenomena provide the structure in which development occurs and the ingredients that help determine developmental course.

The overall affordances in a particular setting help determine the kinds of social interactions that occur and the kinds of transactions between people and the objects within the settings. Development in every domain of human functioning requires productive encounters with the social and physical affordances of one's environment. When the geographic areas where children reside do not afford the resources and structures that allow a child to engage intrinsic motivations, they will likely contribute to lower self-regulation and competence, poorer behavioral adjustment, and a sense of alienation. In some geographic locations, children are far less likely to encounter the resources and activities they need to thrive.

There is growing evidence that low levels of human, social, and material capital connected to one's place of residence can have major consequences for well-being, beginning early in the life course. The effects of geography (neighborhood, population density, region, country) on health begin prior to birth. The impacts on mortality and basic growth parameters are well documented, with evidence indicating that such factors as poor nutrition, poor sanitation, limited availability of good health care, and exposure to teratogens are major contributory factors to overall health.

There is also evidence that living in a poor and dangerous neighborhood or a low Human Development Index (HDI) country can negatively

impact cognitive development and academic achievement. In low-HDI countries and in disadvantaged neighborhoods parents engaged in fewer cognitively stimulating activities with their children. There is also some evidence that living in deprived neighborhoods or low-income countries can contribute to poor psychosocial development, with evidence suggesting that impacts on maladaptive behavior may become more pronounced as children age. The mechanisms responsible for increased maladaptive behavior have not been fully characterized, but there is evidence that low community cohesion and low collective efficacy may be implicated. That said, just as individual poverty has co-factors, so does living in a low-income neighborhood (e.g., parents with mental illness or addiction disorders, low-quality schools, encounters with high-risk peers); thus, it can be challenging to determine whether it is neighborhood risk per se that contributes to poor psychosocial outcomes or whether co-factors of neighborhood SES may be the primary influence.

Research suggests that connections between neighborhood (or community) conditions and children's competence and adaptive functioning are likely to be complex. For example, when Sara Anderson, Tama Leventhal, and Véronique Dupéré examined the issue, they found that living in a neighborhood with a concentration of high-SES families provided some protection against internalizing and externalizing problems, but living in a neighborhood with a concentration of poor families did not increase risk of maladaptive behavior. Another one of the difficulties in assessing the impact of neighborhood poverty and dilapidation is that there tends to be a fairly high level of residential mobility, particularly among urban poor. Residential mobility among the poor is associated with a number of other family factors that make children vulnerable; thus, it is hard to disaggregate the negative effects of living in a poor or dangerous neighborhood from the constellation of other risks family members face. Finally, some of the processes that seem to be implicated in neighborhood effects on children's competence also seem operative with respect to their adaptive behavior.

Indeed, Thomas L. McNulty, Paul E. Bellair, and Stephen J. Watts found that verbal competence mediated relations between neighborhood disadvantage and adolescent violence.

Living in a rural area often means that families have to travel longer distances to access various types of services. Data show that rural families in the United States are less likely to have ready availability of center-based child care and preschool. This may partially account for the lower scores on measures of school readiness shown by children living in rural areas; albeit, the latter finding may also reflect that a high percentage of families living in rural areas are poor and that rural parents tend to be less well educated. That said, findings from the National Assessment of Educational Progress in 2011 showed that while fewer rural eighth graders scored "proficient" on the exam than was the case for suburban eighth graders, a higher percentage of rural eighth graders scored proficient than was the case for eighth graders from concentrated urban areas or small towns.

Generally speaking, rural families are less likely to have easy access to health care, particularly specialists important for prenatal care and serious illnesses and injuries. As it happens, mortality rates for infants and young children are higher in rural areas and children with special health care needs are less likely to be seen by a pediatrician. Indeed, it is not unusual for rural parents who have children with a severe disability or a major health care need to relocate to a more populated area where advanced health care services are available. Finally, children living in rural areas where pesticides and herbicides are used to improve crop yield and children living in areas near mines can also be at high risk for exposure to teratogens that lead to health problems.

Conclusion

For decades, evidence has accumulated showing that experiences connected with family socioeconomic status and place of residence can affect children's development. Negative impacts connected with adverse circumstances can begin at conception and continue throughout the life course, with

impacts manifested in many bio-psychological systems. But care must be taken when attributing performance in any domain of human functioning to low SES or living in an affluent neighborhood or “out in the country.” Human environments are complex; it is often the case that access to one type of resource (e.g., material resources in the home) co-occurs with access to others (e.g., a parent who spends time encouraging a child to learn, good schools, competent peers). Likewise, the experience of one form of risk or adversity (e.g., low household income) often co-occurs with other forms of adversity (e.g., parental mental illness or addiction, living in a dangerous neighborhood).

According to general systems theory, several different conditions (be they assets or risk conditions) can lead to the same outcome. Moreover, theories pertaining to both risks and assets stipulate that it is often the accumulation of risks or assets that accounts for particular end states, not the presence of a particular risk or asset. It is also the case that humans are not mere passive participants in their environments. Humans not only actively engage those environments but they increasingly select and produce the environments they encounter. In this regard two things are important to recall. First, children with different skills and propensities will react differently to the same environmental circumstances. Second, children with certain behaviors or characteristics may evoke particular negative responses from their environment, so that what can appear to be a consequence of negative environmental conditions (e.g., poor adaptive functioning) could actually be partially responsible for creating those conditions. The same is true for positive environmental conditions—a more resourceful child might gradually seek experiences and resources that lead long-term to higher personal SES and/or living in an advantaged location.

In sum, there is reciprocal process involved as regards human environments and human development. Economic and geographic conditions matter for children, but how they matter can vary by child and over time. What seems important from the standpoint of policy is that families be afforded reasonable opportunities to access needed resources.

They also need to be afforded protections when they might otherwise be surrounded by a multiplicity of risk conditions. Given that parents can and do take action in behalf of their children, it seems critical that both parents and children be afforded opportunities to get easily digestible information on how to offset risks and take advantage of opportunities. This latter recommendation would seem quite manageable given the current proliferation of means of disseminating information.

EFFECTIVE ADVOCACY PRACTICES

Effective public policy advocacy has many components and takes many forms. This entry gives an overview of effective practices in early childhood education policy advocacy, with examples of advocacy activities and strategies.

Why should early childhood professionals be involved in public policy advocacy? One of the national standards set by the National Association for the Education of Young Children (NAEYC) for the professional preparation of teachers is the ability to “engage in informed advocacy for children and families and the profession” (NAEYC, 2012, p. 40). Public policy touches early childhood education and educators in multiple ways. A combination of federal, state, and local taxpayer dollars provides subsidies to help children in low-income families reduce their cost of child care so that their families can work and they can be safe and learning. Head Start and Early Head Start funds provide nearly a million of the nation’s babies, toddlers, and preschoolers from its lowest-income families a comprehensive approach to healthy development, education, and parent engagement. A variety of public policies help teachers receive professional development and postsecondary education, sometimes linked to compensation rewards. The Child and Adult Care Food Program ensures children have access to healthy meals and snacks, as well as training and visits to their providers. Most states are increasing their financial contributions to free prekindergarten access with better quality standards.

These are just some of the results of effective public policy advocacy over the last 75 years. Yet there is much more to accomplish. In 2014, states continued to have waiting lists in the tens of thousands for child care assistance. Less than 5% of eligible babies and toddlers can enroll in Early Head Start and fewer than half of the eligible Head Start preschoolers can enroll in Head Start preschool programs. Although states are making progress, quality experiences remain elusive for many children. The woefully inadequate compensation of early childhood teachers in community settings makes it difficult to recruit and retain caregiving and teaching staff with the knowledge necessary to help all young children develop the skills that will make them ready for school and a love of lifelong learning.

Being a policy advocate takes many forms: sending e-mail to a government official, visiting legislators at the state capitol, participating in an

advocacy coalition, and posting alerts on social media. The following section discusses some of the key components of effective public advocacy efforts, highlighted with real examples.

Key Components of Effective Public Advocacy

Diverse Advocacy Voices Working Together on Shared Goals and Message

The successes of advocacy rely on multiple players and multiple strategies for short-term and long-term goals. Having a shared vision and shared strategies among those advocates is key to effectiveness. Legislators and agency directors can easily dismiss multiple competing proposals, but the adage that there is strength in numbers holds true in advocacy so long as the numbers of people are using a shared message.

For the most part, public policy advocacy is led by organizations whose primary mission is policy advocacy (e.g., Children's Defense Fund, National Women's Law Center) or as part of a professional association's mission (e.g., NAEYC, National Association of Elementary School Principals). Increasingly in early childhood, the effective route to public policy results requires a mixture of voices from the field and others whose interest in early childhood education is more indirect. When prominent business leaders and economists speak out for more public dollars for high-quality early childhood education, they bring several important aspects to the shared advocacy: They may have name recognition with policy makers, they are seen as having less self-interest in the issue, and they can bring media attention.

Examples

Fight Crime: Invest in Kids is an advocacy organization composed of sheriffs and other law enforcement personnel who lobby and hold press conferences in support of a greater public investment in high-quality child care, Head Start, preschool, and voluntary home visiting programs. They do not derive a direct benefit from increased

funds for early childhood program access and quality, but they see an important indirect benefit to their work by reductions in crime as demonstrated by studies of high-quality early childhood program access, such as the longitudinal studies of children who participated in the Abecedarian and Perry Preschool programs.

By bringing the respected voices of law enforcement officials together with the traditional voices of early childhood practitioners and researchers, they have a more powerful impact. Policy makers at the federal, state, and local levels often cite the visits and press releases from Fight Crime: Invest in Kids representing law enforcement officers and the Committee for Economic Development representing business leaders as among the catalysts of their interest and support for greater investments in early childhood education.

Understanding Context and Maximizing Opportunity

There is much work to do to achieve to a society with equity of opportunity for all children. Not everything can be tackled at once nationally or locally. Public policy exists in a political, social, and economic tapestry, whether the goal is scaling up a high-quality, state-funded prekindergarten, changing child care subsidy policies, or designing a comprehensive early childhood system.

At the federal level, there are regular cycles of reauthorizations—reviews and revisions to existing laws such as Head Start or the Child Care and Development Block Grant. Policy makers have different responsibilities: the executive branch (the president and agencies, governor and state agencies) can initiate policies and implement policy directives and programs created by the legislative branch (Congress, state legislature). Policy makers also vary in their political ideologies, beliefs, and allegiances.

Sometimes there is a social dynamic that provides a strong foundation for moving an early childhood policy agenda. This can be a larger issue such as welfare reform requiring work or education reform that makes people consider how children are prepared for success in school. Being attuned to

and maximizing the context of social change that can positively or negatively impact policy goals is important.

Example: In the 1980s, women were going to work in numbers not seen since World War II. The women's movement opened up opportunities for women to have careers, and many took advantage of this social shift. To be able to work and to pursue a career outside of the home, women of all incomes needed child care. For the many low-income women who had been working to support their families, they needed not only to find decent quality programs but help to pay for them. The issue was so prevalent in the media that more than 100 pieces of legislation were introduced in Congress. Child care advocates established a formal coalition that worked to produce what became the Child Care and Development Block Grant, which now helps 1.4 million children a month but, unfortunately, only 17% of the eligible children.

Both Data and Personal Stories Matter

"Show me the evidence"—that's what many policy makers tell advocates. Data on access and quality in a policy maker's district or state helps make the case for scaling up successful programs. The National Women's Law Center each year puts out state-by-state updates on child care subsidy policies. The KidsCount Data book, the National Center for Children in Poverty, and the National Institute for Early Education Research annually publish state profiles on a range of child well-being indicators, including early childhood education. State-level advocates also publish information on the impact of policies. Some data come from polls of the public's desire for policy action. The First Five Years Fund conducted a national poll in 2013, repeated in 2014 and in 2015, that showed overwhelming bipartisan support for greater public investment in early childhood education, even if it meant a short-term increase in the deficit or new targeted taxes. Advocates then used the poll information to show policy makers that their constituents would favor these actions.

Data are important, but the personal stories of families and providers are also important. At hearings and briefings, advocates often bring both the research and data experts and a parent or program director to paint a picture of how the policies impact children and families and the ability to provide them with quality experiences. Often, these are the things that the legislators and their staff remember most vividly and that compel them to action.

Examples: The National Institute for Early Education Research (NIEER) was created as part of the Pew Charitable Trusts' 10-year, \$100 million campaign to advance high-quality prekindergarten. NIEER releases annual profiles of states' progress to expand high-quality prekindergarten. The National Women's Law Center issues annually state-by-state information on child care subsidy policies, such as waiting lists and reimbursements rates, that are also used by state and national advocates to urge greater investments in child care for low-income families. Policy makers like having data about children, families, and programs in their states and localities to inform their decisions, but they also like the personal stories that explain how the public investments make a difference and the gaps that remain unresolved. For example, in 2014, Mayor Angel Taveras of Providence, Rhode Island, testified on the Strong Start bill before a U.S. Senate Committee and talked about his personal story as a child who had participated in Head Start and the positive changes the program made for his school and life success.

Early Childhood Professionals and the Public Raising Their Collective Voices

The legislature is not always an advocate's first choice for advancing positive change. Some advocates turn to state citizen ballot initiatives to create a funding stream and policy because the state legislature is deadlocked due to partisan strife or the legislators have not recognized the rising public will for an issue. Ballot initiatives are costly, but when there is known public support for an issue and a recalcitrant legislature or governor, it can be money

well spent. Like other types of issue advocacy campaigns and electoral advocacy activities, its success depends on well-organized advocates following a well-defined strategy and disciplined use of messages with the voters. NAEYC offers a way for anyone—members, others working in the field, and the general public—to be a grassroots advocate. Anyone can sign up for NAEYC’s free Children’s Champions updates and alerts to contact the U.S. Congress using only his or her ZIP code. NAEYC provides sample messages and instructions. For its affiliate leaders, NAEYC provides a 2-day public policy conference in Washington, D.C., that includes a day of senior-level briefings and a day of visits to Congressional offices.

Example: After years of incremental or no progress, a group of community leaders convened in Arizona to draft and propose a ballot initiative designed to create a system of early care and education in Arizona. The initiative, First Things First, set aside a dedicated tobacco tax (approximately \$150 million annually was to create a governance structure and form a regional delivery system). The initiative passed in 2006 with 51% of the vote and then was upheld by 69% of the vote in 2010 when it was referred back to the ballot by the legislature to be eliminated. Both successful initiatives required grassstops (those who have direct access to policy makers due to relationships) and grassroots strategies to be successful. A total of \$4.5 million was raised for both initiatives and was used to fund the needed legal work, polling, media, political strategy, and voter outreach. Examples of the most effective voter outreach included the following:

Targeted direct mail pieces to likely voters with messages that resonated (i.e., male independent voters cared most about the health of young children).

Phone banks organized by nonprofit agency partners using volunteers. All likely male and female Republican and independent voters were called through volunteer efforts.

Social media—with limited funds, social media

were a mechanism to create the perception of a large movement.

Local advocates—with a regional council model, it was effective to engage local advocates to be strong spokespeople and advocates. These local advocates cut across party lines and reflected the diversity of the communities in which they lived.

Media Attention

The media—newspapers, television, radio, Facebook, Twitter—have enormous influence in how the public thinks about an issue. Politicians check their local news, letters to the editor, and editorials to see what issues are trending with their constituents. Traditional print and radio stories, op-ed articles, and editorials have value, especially when they appear in key policy makers’ localities. Engaging the media by giving them story ideas and helping them find people to interview helps build public and political awareness. Social media platforms such as Facebook, Twitter, and Reddit are widely used by advocates and by policy makers and require very little time of grassroots advocates.

Examples: The Strong Start Coalition and Moms Rising held an event on the lawn of the U.S. Capitol in 2013 with a large mock version of the Chutes and Ladders board game with facts about early childhood education and investment needs. U.S. senators and representatives came out and played the game with children and to talk to the press. Organizations that participated, along with members of Congress, posted pictures of the event on Facebook and tweeted about the Strong Start bill with the hashtag #investinkids. The media was invited, and journalists from several media outlets attended, writing stories in newspapers and online publications, giving additional attention to the issue.

Public policies can promote or thwart better experiences for young children and families that produce benefits for everyone. There was never a better time than now to get involved in advocacy at the local, state, and national levels.

EMERGENT CURRICULUM

Curriculum is the how, what, when, and why of a program of study. *Emergent* describes a curriculum approach to early childhood teaching and learning that focuses on children's questions and search for answers. Emergent curriculum unites depth, breadth, and integration of subject areas and developmental domains. The underpinnings of this approach come from constructivist and sociocultural theories. The primary importance of emergent curriculum is the focus on the child as a co-creator of curriculum with the teacher; this creates enthusiastic and engaged learning for teachers and children alike.

Contributions to the Development of Emergent Curriculum

The understanding of emergent curriculum comes through a variety of lenses that expands validity

of this approach in early childhood education. Theorists such as Jean Piaget (1896–1980, a Swiss developmental psychologist) and Lev Vygotsky (1896–1934, a Russian psychologist), though varying in their perspectives on how children acquire knowledge, agreed that children construct meaningful understandings through their experiences. Piaget's cognitive constructivism focuses on how the child builds personal knowledge, based on stages of developing cognitive capabilities. Vygotsky's sociocultural theory highlights culture, language, and social interaction as mediators in how children build knowledge.

These theories can be combined to describe, explain, and, in part, predict how children acquire knowledge in a learning environment where children and teachers collaborate in questioning, discovering, and reflecting. Likewise, the writings of John Dewey (1859–1952, an American educator and philosopher) championed children as capable learners whose knowledge changes through interactions with their world.

Contemporary contributions include those from Italian educators Loris Malaguzzi (1920–1994), founder of the Reggio Emilia approach, and Lella Gandini, present-day teacher, author, and international "point person" for this approach. In an interview in the book *The Hundred Languages of Children*, Malaguzzi captured the essence of the Reggio Emilia approach by explaining, "What children learn does not follow as an automatic result from what is taught. Rather, it is in large part due to the children's own doing as a consequence of their activities and own resources" (p. 44).

Gandini extends these ideas by teaching that the process of learning is ignited by provocations and inspirations, whereby children and teachers discuss ideas from which new understandings emerge. The observation and documentation of what children do and say is the key to teacher dialogue about next steps in learning. Howard Gardner's theory of multiple intelligences supports this approach by explaining the various ways individuals think, learn, and represent their knowledge.

Additional contributions that confirm the status of emergent curriculum have been provided by

early childhood experts Sylvia Chard, Lilian Katz, and Judy Harris Helms. Their development of the project approach emphasizes children's interests and focused investigations. The teacher, as facilitator, plans and structures children's explorations based on child-defined themes. The project approach departs from emergent curriculum with teacher-led orientation to planning and evaluation. In emergent curriculum, children partner in planning and evaluation. They delve into deeper knowledge through evolving dialogue and experiences between themselves and teachers. Elizabeth Jones, of Pacific Oaks College, and Margie Carter and Deb Curtis, early childhood trainers and consultants, provide further description and guidance for implementation of emergent curriculum.

Benefits of Emergent Curriculum

Early childhood curriculum should be meaningful and reflect the needs of children in order to enable success in school and in life. Emergent curriculum benefits children, teachers, families, and communities. Research has documented important benefits for children that

- acknowledge children as active participants in their own learning;
- provide opportunities for children to take increasing responsibility for their own learning;
- motivate children to learn through participation in the planning of topics based on their interests, questions, and abilities;
- develop problem solving that enhances thinking skills and leads to deep and complex knowledge;
- enhance the development of self-expression, oral and written language, and creative abilities; and
- foster lifelong learning.

Likewise, studies of emergent curriculum have shown benefits for families and communities that

- allow genuine participation that supplies the diverse cultural knowledge unique to each setting;
- encourage effective communication about children's learning and the contributions of family and community priorities and ideas; and

- meet expectations for a child-responsive program in which children are engaged and enthusiastic about the program and learning.

Teachers employing the emergent curriculum have opportunities to

- integrate learning across all developmental domains through play, real-life activities, routines, and transitions;
- provide continuity connecting children's prior knowledge to new learning that leads to deeper understandings about topics of interest;
- challenge and support children to explore many ways of explaining and representing their ideas;
- develop and teach a curriculum that is dynamic, evolving, and child-centered;
- document and assess learning connected to a child's personal knowledge, abilities, and dispositions that align with education standards and curriculum requirements; and
- encourage professional development and strengthen teaching through reflection on practice.

Disadvantages of Emergent Curriculum

There are several cautionary disadvantages to emergent curriculum. There are two overarching considerations. First, when emergent curriculum is blended with other curriculum models on a trial basis, unexpected or unmanageable outcomes impede rather than promote learning. Second, if teachers are unclear about developing curriculum together with children, then curricular outcomes may be less than optimal—teacher learning may be diminished, child learning may go undocumented, or teaching and learning may become haphazard. The following list details additional barriers that, if addressed, may allow for full implementation of emergent curriculum.

Curricular Middle Ground Challenge. Elizabeth Jones describes emergent curriculum as a curricular middle ground between teacher- and child-directed curricula. In order to arrive at this middle ground, the teacher's intentions for engaging children must

be led by children's choices and their identity as capable learners. Children's awareness, questions, and exploration, then, will drive the *emergence* of inquiry, investigation, and discovery. This means that the locus of control for defining the source, processes, and evaluation of emergent curriculum must be shifted in the direction of the child.

This does not omit teacher contribution; rather, a *locus of control shift* rebalances the responsibilities for constructing the curriculum among participants—adult or child teachers and adult or child learners. One challenge is that most schooling systems see adults as only teachers and children as only learners. Likewise, teacher training often stresses that the teacher be “in charge,” so relinquishing even some control to children runs counter to what teachers are taught, to what administrators look for, and to many societal expectations. If the challenges of working in partnership with children, optimizing balanced control, and achieving mutually valued outcomes are not met, then exploration, communication, or participation may become only a means to measurable skills or standardized achievement levels rather than lifelong learning.

Teacher Disposition, Skills, and Values. Emergent curriculum intertwines various teaching–learning roles, modes, and outcomes, making it inherently complex. Teacher disposition, skills, and values are influences that impact the implementation of emergent curriculum. Teaching intuitively, a disposition, often makes it difficult for the creative teacher to translate how and what children learn into historically conventional terms for children, parents, colleagues, policy makers, or the public. A teacher's skill may be limited in sparking learning through co-constructed curriculum *with children*, which involves intentionally unscripted interactions and careful observation. Emergent curriculum demands that the teacher be steadfast in valuing the child as an active partner in the learning process. However, these teacher characteristics are not easily acquired without extensive practice.

Reliability. Typically, emergent curriculum is a one-of-a-kind teaching–learning experience. It is a set

of uniquely evolving and interrelating explorations with a single group of children. Sensitivity to each new group's learning styles and capabilities may hamper duplication of the exploration. While parts of an investigation might be repeatable, learning cycle nuances that include awareness, exploration, inquiry, and utilization of new knowledge are likely to vary. This means that emergent curriculum is not conventionally reliable in terms of producing finite measures of learning.

Accountability Confusion. Emergent curriculum does not define measurement for accountability. Widely accepted thinking about quality schooling stresses that the child receives knowledge and prescribed lessons yield discrete, easily measurable learning units. Often, test scores to measure achievement are the primary means to justify educational budget expenditures. In contrast, emergent curriculum uses photographic and narrative documentation to detail changes in children's learning over time. Therefore, emergent curriculum may be difficult to justify in terms of cost–benefit to policy makers and educational funding sources.

Implementation of Emergent Curriculum

To implement emergent curriculum, researchers and practitioners have identified four key elements: (1) teacher dispositions, skills, and knowledge; (2) the learning environment; (3) the roles of the child and teacher; and (4) partnerships and relationships. With a curriculum that is continuously evolving, dispositions include the willingness to document and tolerance for ambiguity. Skills include observation, documentation, and interpretation. A thorough understanding of child development in all domains and knowledge of benchmarks for academic and developmental expectations comprise the essential teacher knowledge base. Teachers need to value and know (through initial preparation and ongoing professional development) how to gather, organize, and evaluate data about children's learning

across an array of environments, communication methods, and accommodation strategies. Then, they can confirm the extent to which children meet educational standards and expectations for continuous intellectual and developmental growth.

The learning environment, as a teaching force, reflects the local community and allows for flexibility and play. The physical and emotional environment provides a blend of ideas, ethics, attitudes, and cultures. Ambiance and aesthetics offer a welcoming and secure sense of place. One hallmark of emergent curriculum environments is the use of open-ended materials, which lead to the multi-use or unexpected use of space and supplies. The use of time and space match the direction and intensity of the children's engagement. This means that objectives may be adjusted as learning progresses. Likewise, play provides suggestions for topics plus an avenue of learning. The social learning that accompanies play generates important lifelong lessons and perspectives on sources of knowledge.

In the co-constructed emergent curriculum, teacher and child have distinct as well as shared roles. The Reggio Emilia approach details the teacher's distinct role as provocateur, researcher, and learner, and the child's distinct role as a capable learner and decision maker. The observation and documentation of children's play, as employed by a teacher-researcher, furthers learning by suggesting provocative questions for investigation. This questioning increases the likelihood for teachable moments.

Through careful listening to play interactions, the teacher-provocateur learns the depth of interest and current level of knowledge about children's interests. An example of a provocative question is found in this scenario: While children are exploring the color blue, the teacher asks "What makes things blue?" The child, an independent learner with personal funds of knowledge, is able to draw meaning from experiences and make decisions that propel learning forward. Both teacher and child utilize questioning to further the learning process and use a variety of means to represent and interpret the learning.

Child-directed and play-based emergent curriculum embraces open and reciprocal relationships

with all members of the program community—teachers, children, families, and the local community. The establishment and maintenance of trust is fostered with communication and dialogue about the status of the curriculum and learning.

EMOTIONAL DEVELOPMENT

Emotions have traditionally come first in the early childhood field. The history of early childhood education reflects strong influences from theories that have emphasized emotion-related issues: psychosocial development, the importance of close relationships with parents and other caregivers, and children's feelings as the foundation for long-term development. In the face of mounting pressure to prioritize academic skills, early childhood professionals have long argued in favor of nurturing children's emotional lives.

More recently, compelling research evidence has been available to support the beliefs and experiences of early childhood practitioners, while also creating a more nuanced, complex picture of emotions' contribution to overall development and learning. This entry describes the key components of emotional development, traces influences on their emergence, and identifies effective strategies for preventing and addressing young children's emotional difficulties.

Functions of Emotions and the Components of Emotional Development

What Are Emotions For?

Emotions are at the core of human experience and human development. In every culture and period of history, people have experienced the same fundamental positive and negative emotions, including joy, interest, surprise, fear, anger, sadness, and shame. Emotions evolved for a purpose: These feelings motivate human beings to connect with others and take action. Even very young children experience and can express basic emotions. However, children's emotion-related competencies expand over time—in the process known as emotional development.

Components of Emotional Development

Components of emotional development include emotion expression, emotion understanding, and emotion regulation. Specifically, emotional development includes children's growing ability to

(a) understand their own emotional state, (b) understand others' feelings, (c) use culturally appropriate words to describe feelings, (d) feel empathy for others, (e) understand that sometimes inner feelings and outward expression are not the same, and (f) regulate one's feelings of distress or other intense emotions (emotion regulation). Taken together, these and other abilities contribute to children's overall emotional competence.

Why Is Early Emotional Development So Important?

Even when they are very young, children differ in their emotional competence and in the risk that they may develop emotion-related difficulties as they grow up. These differences have important consequences. If emotional development is not progressing well, it can have a ripple effect on other domains. A few examples illustrate this point. Children who misinterpret their classmates' feelings (thinking other children want to hurt them when they just want to play) will find it hard to make friends and may be bullied or bully others. Children who cannot regulate their own feelings of anxiety or frustration may avoid new, challenging learning opportunities that could support their academic competence. Children with persistent challenging behavior are usually less engaged in classroom activities, do less well in preschool, and cause their teachers high levels of concern and stress. In contrast, emotionally competent children are more likely to be accepted by other children, to take advantage of learning opportunities in the classroom, and to achieve academic success as they move through school.

Major Influences on Young Children's Emotional Development

Influences within and beyond the family can support, or sometimes undermine, the development of emotional competence.

Family Influences

Secure, nurturing relationships with parents or other family caregivers provide the basis for positive

emotional development. Within the family, young children also begin to learn “emotion language,” learn appropriate ways to express and regulate emotions, and learn to discern other family members’ feelings—all part of the important process of emotion socialization.

Influences Outside the Family

With the vast majority of young children spending time in child care, pre-K, and other programs, supporting early emotional development becomes an important responsibility for those outside the family as well as for parents.

Although most early childhood classrooms have a tone that is emotionally positive, some educators ignore or disrespect children’s feelings. Many educators do not take full advantage of opportunities to intentionally teach emotion regulation skills, emotion understanding, and other components of emotional development.

Young Children Whose Emotional Development May Be at Risk

Some children may be at special risk of not developing key emotional competencies, including critical skills in emotion regulation. For example, emotional regulation may challenge children who have been diagnosed with autism, Down syndrome, or other disabilities and developmental delays; children who grow up in abusive or emotionally neglectful environments, or in families in which a parent is depressed; and children whose teachers treat them distantly, harshly, or disrespectfully because of their socioeconomic or ethnic background.

Contemporary Initiatives and Interventions to Promote Positive Emotional Development

Fortunately, even children at risk of maladaptive emotional development can flourish when emotional competence is made a priority. A number of federal and state standards, as well as early childhood programmatic initiatives, are explicitly addressing emotion-related outcomes.

Emotion-Related Outcomes in Federal and State Standards

At the federal level, Head Start’s Child Development Outcomes Framework includes Social and Emotional Development as one of its six domains. Within this domain, the subdomains of Self-Regulation and Emotional and Behavioral Health are the most emotion-relevant. Head Start provides staff with research-based resources and recommendations for classroom strategies to support development in each of these areas.

All 50 states and some territories have standards or early learning guidelines (ELGs) describing desired outcomes for preschool-age children. All of these states address social and emotional learning in some fashion, usually through a distinct “social and emotional” or “socioemotional” category (in contrast, only one state—Illinois—has a free-standing social and emotional learning category in its K–12 standards). Typically, social skills are emphasized more in these standards than are emotion-related skills. Specific emotional development standards and indicators vary from state to state, with some apparently guided by research on emotional development (e.g., including indicators of children’s ability to develop relationships with adults and peers). In contrast, other states have limited the domain’s scope to emotional self-regulation and compliance with rules.

Programs to Promote Positive Emotional Development and Address Children’s Emotional Challenges

General Early Childhood Curricula and Teaching Practices

Emotional development goals are emphasized explicitly in many widely used, comprehensive early childhood curricula. Often these curricula identify ways that teachers can use activities such as dramatic play, puppets, music, sensory experiences, and creative art to help children understand and express emotions and work through specific emotional issues.

Everyday teaching practices, aligned with the principles of developmentally appropriate practice,

can support children's emotional competence. Consistent with emotional development research, educators can find opportunities to build warm personal relationships with individual children, model appropriate expressions of emotion, identify and name children's feelings, talk about the reasons why people feel the way they do, offer many opportunities for pretend play (which has been found to support emotion regulation), take seriously children's distress while helping them learn to self-regulate, give children ways to help their classmates feel better when they are upset, recognize and honor individual or cultural ways of expressing emotions, and carefully assess children's emotional development so that the results can be used to create more supportive environments for all children.

Programs Specifically Targeted Toward Emotional Competence

In addition to embedding emotion goals within comprehensive curricula, several curricula or other intervention programs have been developed to specifically promote emotional competence or, somewhat more generally, social-emotional competence. These include the Preschool PATHS curriculum and the Incredible Years curriculum. In an ongoing, large-scale randomized trial, the Head Start CARES demonstration project is examining the effectiveness of these programs along with a third approach (Tools of the Mind, a more comprehensive curriculum with a strong emphasis on the use of make-believe play to promote self-regulation).

Current interest in these kinds of programs, including careful evaluation of their effectiveness, reflects increased attention to emotional development as a critical domain in early childhood and increased understanding that well-planned, intentional intervention is important, especially for children who are at risk of emotional difficulties.

There does not appear to be one curriculum or one prevention program that has the answer. Reviews of research and recent evaluations suggest a few guidelines. First, effective programs need to be grounded in sound theory and research. Second, beginning early—preventing problems before they

begin—is best. Third, effective programs often combine direct, intentional teaching of emotional skills (such as recognizing or regulating emotions) with many informal opportunities to experience and practice emotional and social learning. Along with these priorities, teachers, family members, and others need to be supported with professional development, skilled coaching, or other resources so that the curricula or other programs are well implemented. Finally, as with most other kinds of interventions, programs that are implemented over time, ideally over multiple years, are more likely to be effective than isolated lessons.

Conclusion

Attention to young children's emotional development has taken on greater urgency as early childhood services receive renewed attention from the public and policy makers. Increased numbers of young children who may be at risk for emotional difficulties because of poverty, family violence, disabilities, and other risk factors are entering prekindergarten, Head Start, and other preschool programs. As children grow up, the consequences of failing to address emotional development may be seen in school failure, antisocial behavior, mental health issues, and community violence. Early childhood professionals need to implement and rigorously evaluate programs that promote positive emotional development and address emotional difficulties in the early years. At the same time, current and future teachers need enhanced professional development, including ongoing coaching and mentoring, so that they can incorporate evidence-based approaches into their practice. Finally, in drawing implications for social policy from the emotional development research, Cybele Raver (2002, p. 1) concludes that “while young children's emotional and behavioral problems are costly to their chances of school success, these problems are identifiable early, are amenable to change, and can be reduced over time”—encouraging news for administrators, policy makers, teachers, families, and the children themselves.

EMOTIONAL DISABILITIES AND ASSESSMENT

Young children demonstrate skills across a variety of domains. The play and language of young children are measured through direct observation and can easily be compared to developmental checklists and milestones. However, the emotional and behavioral skills of young children are not always so easy to assess. There are myriad circumstances and situations that make the identification of young children with emotional disabilities a challenge. However, given the recent studies indicating that young children with social-emotional problems persist to school-age settings, there is a need to examine the assessment and identification process in order that intervention can occur swiftly and appropriately for young children.

If a child's emotional competence is of concern, the parent/caregiver or other professionals can make a referral to a state agency based on the child's age (i.e., birth to age 3, preschool, school age). Once the referral is made, there are numerous screenings needed to rule out other factors that may influence the child's emotional and behavioral competence.

Screenings

Ordinarily, a hearing and vision screening would occur early in the process to ensure that the challenging behaviors were not a result of a sensory delay. These screenings can occur at the pediatrician's office or other medical provider.

Prereferral Interventions

Once required screenings and evaluations are completed, a multidisciplinary team should be convened to examine all required screening data and teacher or parent/caregiver information.

During this prereferral conference and meeting, teachers and parents/caregivers should review all pertinent data to determine if a causal relationship can be found for the emotional or behavioral challenges. If so, child- or classroom-specific interventions should be developed by the team to support the child. Additionally, while supporting the child is very important, so is the support and guidance to the teacher or parents to ensure the interventions are implemented with integrity and fidelity.

It is important to note that when selecting an appropriate intervention strategy, it is imperative that a research-based intervention be selected. Such interventions have a strong pedagogy and empirical backing to be shown effective in changing behaviors for young children. These interventions often require training for the child in the acquisition of skills in language, cognition, or social skills, or to support the all-around learning and growth of the child. Simultaneous, classroom teachers and parents need assistance in environmental or curricular modifications. Often parents or teachers will need training to implement targeted interventions. This training may come from the school support team or at the school district level. It is not the responsibility of the family to seek such supports and trainings on their own.

The interventions must be individualized specifically for a student and a particular behavior, even when implemented within a classroom. Further, the behavior intervention should be implemented for a minimum of 3 weeks, ideally up to 6 weeks, with daily data collection on behavior recorded daily. When collecting data, it is important to record data in terms of frequency, duration, and intensity.

Evaluations

If the team determines that the intervention was not effective, however, it is necessary to refer for a full education and behavioral-emotional evaluation. These evaluations will be conducted at the school, typically by the school psychologist and school faculty. The behavioral-emotional evaluation is conducted to document whether there are

deficits in emotional function or coping skills. These evaluations can take many forms but often include student interviews, completion of checklists or rating scales by teachers and parents/caregivers, or observational data.

In addition to the behavioral-emotional evaluation, a comprehensive education evaluation will be conducted by a certified psychologist, special educator, or other trained professional. These evaluations would include a full assessment of the classroom environment, the student's strengths and weakness, achievement testing, present level of academic functioning, and curricular information. This information should provide a global picture of the child's academic, social, and behavioral performance across the child's entire school environment and learning day.

Additionally, a complete psychological evaluation should be conducted by a certified or licensed psychologist. This evaluation will provide valuable information as to the student's overall academic achievement and behavioral history. Often this evaluation is accompanied by an intellectual evaluation when learning challenges or giftedness is suspected. A social/developmental history adds to the richness of the evaluation by providing a summary of all information collected during the prereferral process. This information includes interviews with parents/caregivers and teachers, which highlight the academic and behavioral developmental profile of the child. The thoroughness of this evaluation will assist team members in documenting both normal and abnormal developmental events. Finally, a communication evaluation is often conducted to include a comprehensive assessment of a child's expressive and receptive language skills.

After all evaluations are completed, an individualized education program (IEP) team will meet to discuss the results of the evaluation, placement considerations, and potential for supports from the special education program through an IEP. The team must include parents of the child, a regular education teacher, a special education teacher, a representative from the local education agency, and an individual able to interpret the testing evaluations as

well as the instructional implications from the evaluations. Any other person may be a part of the team at the discretion of the parents or local education agency. The team will meet and present the results of the comprehensive evaluation to determine eligibility for *emotional disability*.

The federal definition of *emotional disturbance* is

a condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree that adversely affects a child's educational performance:

(A) An inability to learn that cannot be explained by intellectual, sensory, or health factors.

(B) An inability to build or maintain satisfactory interpersonal relationships with peers and teachers.

(C) Inappropriate types of behaviors or feelings under normal circumstances.

(D) A general or pervasive mood of unhappiness or depression.

(E) A tendency to develop physical symptoms or fears associated with personal or school problems.
(CFR 300.8 (c)(4)(i))

In determining eligibility, team members must examine several facets of the federal or state definitions. The federal definition is broken down below to address various types of assessments needed throughout the process.

First, the condition must be present over a long period of time. Although a recommended amount of time is not specified and can vary across circumstances, the team must utilize professional judgment to determine that the amount of time is sufficient to determine a pattern of behavior and need for supports. The pattern of behavior cannot be the result of a single traumatic event, response to a situational crisis, or other behavioral outbursts expected to subside over time. The appropriate amount of time will be dependent on the child's age and developmental level and will be at the discretion of the IEP team.

Another aspect of the federal definition is that the condition must be exhibited to a marked degree. Regardless of the behavior, in order to be

eligible for special education services, the behavior must occur at a greater frequency, intensity, or duration than that of students in the general education classroom. Additionally, these behaviors must be exhibited across multiple environments and not related to specific circumstances, teachers, or academic areas. Given that this documentation is a key factor in determining eligibility, it is essential when developing prereferral interventions that special considerations be made in order that data can be collected on the behavioral frequency, intensity, and duration.

Further, the behaviors must have an adverse effect on the educational performance. Therefore, the full-scale educational and psychological evaluations are key components to be certain there is not an intellectual, sensory, or health factor manifesting the behavioral challenges. However, if there are noted intellectual, sensory, or health factors, the team must determine that these conditions are not the primary determining factor of the child's lack of progress. For example, a child may have learning disability, but the team must demonstrate that it is the emotional disability, not the learning disability, as the primary cause of the lack of educational progress.

Characteristics

As referenced in the federal definition, a child must exhibit one or more characteristic over a long period of time. The five characteristics are outlined and discussed below.

An inability to learn that cannot be explained by intellectual, sensory, or health factors. As mentioned previously, a child's lack of educational progress cannot be a result of an intellectual, sensory, or health-related factor. Further, this progress is based on a child's individual learning potential. This potential is determined by the educational and psychological assessments conducted. For the identification of emotional disturbance, a child's issue must be so severe that he or she could not be adequately served in the general education setting alone.

An inability to build or maintain satisfactory interpersonal relationships with peers and teachers. For identification under this characteristic, there is a need for significant documentation from a variety of sources. Therefore, it is essential that assessments and data collection of both supports and behaviors are systematically collected and analyzed to determine if such a deficit occurs. Although behavioral outbursts are easiest to document, there is also a need to examine extreme social withdrawal and social isolation. Again, these behaviors, both passive and aggressive, must occur across the day and social groups.

Inappropriate types of behaviors or feelings under normal circumstances. To be eligible under this criterion, when under normal conditions and environments across time a child must exhibit significant and inappropriate behaviors. The behaviors are easiest to document because they are clear in action. These behaviors can include, but are not limited to, overreaction to environmental stimuli, obsessive or compulsive behaviors, and extreme verbal outbursts. However, identifying feelings is difficult because they can be subjective. Therefore, the assessment needed to document such issues must be clear and consistent. Often data collected through personal interviews, projective psychological testing, and targeted observations can be valuable assessment information.

A general or pervasive mood of unhappiness or depression. Again, the assessment of this characteristic can be difficult because a child will often mask these feelings with angry or aggressive outbursts. Therefore, student and teacher interviews are a key assessment for this area. Keeping records of behaviors such as withdrawal from friends or desired activities, frequent crying, or anxiety will be helpful in assessing the presence or absence of depression.

A tendency to develop physical symptoms or fears associated with personal or school problems. Often a child may develop physical symptoms related to the challenges she or he is facing. To be

a qualifying element, these symptoms must meet the same standard as the definition (i.e., marked degree, long period of time). Additionally, the physical manifestation needs to be assessed to determine if it is of psychosomatic origin.

Once all assessments are considered and if criteria are met, a child may be identified with an emotional disturbance. Continual assessment of student progress will be needed for a child to reach his or her learning and behavioral potential. A yearly IEP meeting will provide a benchmark and a timeline, and ongoing assessments will provide documentation for progress monitoring and identifying any changes that may need to be made to a child's IEP.

Conclusion

Although identification of young children with emotional disturbance is a long process, it is a necessary one. Assessments are key in the early identification leading to appropriate services and supports that may lead to the reduction of problematic behavior. A variety of assessment tools are required in order to create a broad and comprehensive picture of the child's social and academic abilities and needs. Many times, interventions put in place after the initial assessment provide enough support for a child and his or her teacher to address the challenges successfully.

EMPATHY

The word *empathy* is derived from two Greek words, *empátheia* (affection) and *páschein* (to suffer); based on these origins, the term refers to recognition of someone else's pain or distress. There is a useful distinction between empathy and sympathy. Sympathy is the emotion of pity or feeling sorry for someone else while empathy relies on higher levels of emotional identification with and understanding of difficulties and suffering experienced by others. Contemporary definitions of empathy have taken it a step further by linking it to positive action; therefore, what counts as evidence of empathy is compassionate action intended to support the person in distress. Furthermore, genuine empathy relies on emotion regulation to some extent because, in order to truly help someone else, the empathic person has to adjust his or her perspective and actions when others do not feel the way that he or she expected; otherwise, the prosocial behavior does not have the desired effect. Thus, empathy is more than feeling for someone else; it is a multicomponent construct with affective, cognitive, and behavioral dimensions.

As reflected in the research of Carolyn Zahn-Waxler, Martin L. Hoffman, and Nancy Eisenberg, there are linkages among empathy and compassion, moral development, caring, and altruism. The field of early childhood education places a high value on empathic behavior, both as an outcome for young children enrolled in early childhood programs and as a professional disposition of teachers and teacher educators.

Importance of Empathy Development for Young Children

The development of empathy depends on recognition of others' pain or distress, parallel emotions, understanding of others, emotion regulation, and social initiative. One model for understanding empathy comes from Mark H. Davis; it includes antecedents (variables from within the person such as temperament as well as contextual influences, such as the emotional impact of the specific situation); processes (both noncognitive, such as mimicry, and cognitive, such as making judgments about the other person's mental state); intrapersonal outcomes (affective and nonaffective); and interpersonal outcomes (such as helping or prosocial behavior). Children's empathy development is important for at least three reasons.

First of all, the roots of empathy manifest in infancy; empathy is arguably the earliest emotion to surface in human beings. Indeed, the early emergence of empathy in human beings has given rise to debates about whether or not the capacity for empathy is, to some extent, innate. One phenomenon that is cited as a precursor of empathy is a commonly observed response of newborn babies in a hospital nursery: When one baby starts to cry, others join in crying. This rudimentary response to others' distress is sometimes cited as evidence that a capacity for empathy is hardwired into the human brain as part of the need to affiliate with others. Interestingly, this reactive crying is elicited more by the cries of peers than by a recording of the infant's own cries, the cries of a chimpanzee, or other loud sounds. During toddlerhood, it is possible to observe more sophisticated behavioral repertoires that children use to react to pain and need in others. Often, this is accomplished by having the child's mother pretend to be injured and noting the child's facial expressions, emotional congruence, and efforts to comfort the caregiver. Gert-Jan Vreeke and Ingrid van der Mark posit that, upon a child being confronted with a caregiver's injury and tears, there is a progression along the lines of the following: recognition (She is in pain.), appraisal (Could/should I help?), identifying a course of action (How can I help?), and evaluation (Did she find me helpful?).

Second, because empathy is a social disposition, it develops over an extended period of time and is learned primarily through opportunities for the child to be on the receiving end of empathy and to observe other empathic encounters. Family variables such as the quality of attachment between parents and children, the parents' capacity for identifying with their child, methods of child guidance that are sensitive to the child's needs, and expectations for the child's behavior in various situations all appear to exert an influence on when and how the child's empathic behaviors emerge. Young children tend to need concrete evidence of need in others. So if a toddler sees a parent or teacher comforting a child who is crying with a hug and the offer of a tissue and, if the same visual cues (i.e., sad facial expression, crying, sobbing) are present, the toddler is more likely to emulate the empathic behavior. Even before children know what to do to help another in obvious distress, they may enlist help from an adult in response to another child's distress.

The third reason that empathy development in early childhood is so important is that the early childhood years are formative; in other words, early experience affects later experience. Empathic behavior is learned gradually in the context of social relationships. In the absence of such relationships, a person's full potential to respond to others in compassionate and helpful ways can be adversely affected. Perhaps the most persuasive argument for emphasizing empathy in the early years is to consider what happens when it fails to develop adequately. During childhood, deficits in empathy frequently are linked to aggression and conduct disorders. From a psychological perspective, a person with very low levels of empathy would be likely to exhibit antisocial behavior, feel little concern for others, and have no remorse about the harmful (and possibly criminal) actions he or she has taken against others. Therefore, developing empathic behavior in young children is widely regarded as a way of exerting a positive influence on society. Efforts to improve society through education (e.g., multicultural education and inclusion) advocate not merely for knowledge

about others but also for positive social action on behalf of those who have been marginalized and mistreated.

Issues About Teaching Empathy to Young Children

From Friedrich Froebel's first kindergarten to the schools of Reggio Emilia, guiding young children's social and emotional development has been a priority in early childhood education. Across the ages, respected leaders in the field of early childhood education have recognized the importance of building a sense of community among children and with families. There is little question that young children must learn to be compassionate and kind because, when these skills are lacking, it is difficult to form enduring, positive relationships with others. Controversies persist, however, about where responsibility for this teaching rests. Some families support teaching empathy as part of the early childhood curriculum, while other families feel that educators are overstepping their bounds and venturing into moral and/or religious teaching that is the province of family and faith, while others still may not, for a variety of reasons, ascribe the same value to their children learning to demonstrate empathic behaviors.

A second persistent debate about empathic behavior is whether, when, and how it can be taught. To date, most intervention efforts that have empathy development as a major goal have tended to focus on older students. A major recommendation from the National Institutes of Health (NIH) was to begin teaching prosocial skills much earlier to prevent children from becoming aggressive. In the past, empathy-building strategies were more likely to be infused into existing curricula; however, given the growing international concerns about cruelty and violence, the number and type of programs intended to promote prosocial behaviors (e.g., character education, bullying prevention, peace education, humane education) have increased. However, empirical research on the salutary effects of such initiatives is difficult to conduct and limited.

Evaluation research on the interventions often is criticized for neglecting to conduct a preassessment; relying on self-, family-, or teacher-report; gathering data over a short period of time; or failing to compare the relative effectiveness among existing programs.

Empathy in Early Childhood Educators

Empathy is of particular importance for early childhood educators in two major ways: first, as a prerequisite for fostering positive human relationships and second, as a way to address young children's challenging behaviors.

Empathy in Preservice and In-Service Teachers

The importance of effective partnerships with children, families, and community members as well as with colleagues and professionals from other fields depends, to a considerable extent, on the early childhood educator's empathic response. Therefore, developing a professional disposition of empathy for others is a major goal of early childhood teacher education, not only with preservice educators enrolled in teacher preparation programs but also with in-service educators pursuing professional development. It is critical that the early childhood educator's empathy extend not only to those perceived to be like herself or himself but also to those who are regarded as very different; to do otherwise compromises the early childhood educator's ability to work successfully with diverse groups of children and adults. If an early childhood educator cannot fully appreciate others' circumstances and/or refrain from being judgmental then reciprocal trust, mutual respect, and open communication cannot occur. Thus, deficiencies in empathy are a major obstacle to successful partnerships.

It is important to note, however, that it is possible for a teacher whose behavior was initially empathic to erode, a situation referred to variously as compassion fatigue or burnout. A decline in empathic behavior tends to occur

when an individual becomes too preoccupied with personal stressors to recognize the feelings of others, share in the feelings of others, communicate compassion for others' difficult situations, and choose a response that others find supportive and helpful. If early childhood educators are to become more, rather than less, empathic across their careers, they need to make deliberate efforts to sustain and increase empathy through activities such as engaging in reflective practice with responsible colleagues or seeking out professional development opportunities. Maintaining a high level of empathy for others is foundational to exemplary service as an early childhood educator, as reflected in the Code of Ethical Conduct and Statement of Commitment of the National Association for the Education of Young Children.

Young Children's Challenging Behaviors

Challenging behavior—a general term that refers to disruptive, aggressive, and violent behavior that inflicts mental or physical harm to others—has become a major concern of educators throughout the world. In international surveys, challenging behavior has been identified as one of the most pressing issues within the community of early childhood educators.

Early childhood is widely acknowledged to be the time when violence, aggression, and antisocial behaviors in human beings are most responsive to interventions. One trend in the research is that empathy is negatively correlated with aggression. This makes the early years an irreplaceable opportunity to teach empathic behaviors and exert a positive influence on the trajectory of empathy development in the individual. From the perspective of evolutionary and comparative psychology, empathy is foundational to progress toward becoming a more civilized society. Until or unless people widen the circle of other individuals and groups to whom they extend concern, compassion, and genuine care, society cannot become more just and humane.

ENGAGING CONVERSATION

Engaging conversation refers to a verbal interchange between two or more people on a shared topic that holds the interest and attention of participants. Children are introduced to this communicative form through interactions with others in their social worlds, often starting with adults, but also with peers and siblings. This entry reviews the research on the nature of engaging conversations in the home and school contexts, considers the implications of children's home experiences for their school success, and identifies the ways in which schools can use conversations to further educational aims.

Conversations are characterized by the relatively equitable exchange of thoughts, opinions, and questions on a particular topic through organized turn-taking. While both participants actively shape the direction of the conversation, each comment is related in some way to the one that came before. Children engage in conversation both at home and

at school, although the nature of the interaction varies across contexts.

Theoretical Framework

Human conversation is generally understood through the lens of Lev Vygotsky's sociocultural theory of development. This theory holds that culturally valued skills and understandings are conveyed through social interactions. Conversations are a particular type of social interaction that is predicated on joint attention to a particular topic or event and shared communicative intent. These interactions provide a particularly rich opportunity for adults to scaffold children's understanding, by creating an exchange of information and ideas that falls within what Vygotsky called the "zone of proximal development." The adult can set the demands of the task just slightly above the child's competency to support skill building and provide information and coaching to improve performance as needed. Through these mechanisms, conversations serve as opportunities to deepen understandings, develop skills, and create a sense of connectedness.

Research

Learning to Converse

Skilled conversation is a complex task, and children need to master a set of pragmatic language skills that support fluent conversations. They must learn to take turns with another (or multiple) participant, share the floor, stay on topic, show attention, and monitor and repair misunderstandings or confusions. Adults can facilitate early practice of these pragmatics in pre-verbal infants through proto-conversations, in which the adult and infant take turns verbalizing, with the mother providing examples of fluent speech. When children are just learning to talk, adults do most of the work in conversations, asking questions, encouraging the child to contribute, and then elaborating on the often one-word contributions of the child. These conversations rely heavily on the adult's understanding of the child's experiences, perspective,

and knowledge to interpret the limited contribution of the child.

As the child's skills grow, the adult reduces interpretive support and makes more requests for clarification to encourage the child to participate more actively and provide more explicit information. Children are increasingly expected to independently manage turn-taking, which requires an understanding of the implicit, culturally specific rules for these interactions as well as the self-regulation to follow them effectively.

Parent-Child Conversations

Parent-child conversations often focus on discussing events in the past, present, and future; sharing and constructing personal narratives; planning dramatic play; talking about books; and reviewing social norms and rules. These can occur at any time, but mealtimes, playtimes, and shared book reading activities are particularly rich opportunities. During these events, discussion of the non-present (e.g., past experiences, events in a book) is likely to occur and the skillful use of decontextualized language that explicitly communicates all information necessary to understand becomes important.

Decontextualized language relies on a more sophisticated vocabulary and more complex syntax, making it an important vehicle for developing children's language competencies. Extended conversations, in which parents encourage children's participation and provide elaborated responses to their contributions, lead to parental modeling and child practice of more complex speech. The complexity and diversity of parental speech, as well as the extent to which it is contingent on children's contributions and responsive to children's interests, is positively related to the development of children's oral language skills.

Different types of conversations have been shown to be important for other domains of development beyond language. Extended conversations about books develop children's reading comprehension and emergent literacy skills. The co-construction of personal narratives shape children's sense of

identity, while allowing for the integration and negotiation of social norms and expectations. The extent to which a parent talks about emotional states and provides information about differences in beliefs, preferences, and understandings of others helps children improve their perspective taking and social competence.

Conversations may carry explicit pedagogical intentions, as well. Parents sometimes discuss processes and physical phenomena with children, such as might occur when visiting a museum or cooking together. Through a conversational back and forth, parents learn what the child knows and does not know, so as to identify and fill in missing information. These exchanges can support a deeper understanding of causal relationships, greater knowledge about the world, and increased skill at using higher mental processes. Although pedagogical conversations are sometimes begun by adults, children in North American and European countries frequently seek out these conversations by asking questions about the things in the world and their experiences that have sparked their curiosity. These efforts are often successful at initiating extended conversations by eliciting explanations from parents, although parents in some non-Western cultures are less likely to provide explanations.

Parents vary greatly in the nature of the conversations they have with children. Some are very talkative, use rich language, elaborate on their children's contributions, and encourage extended conversation, while others say little and focus on behavior management. There is some evidence that these differences relate to socioeconomic status (SES) and that the differences in maternal language largely explain SES-based differences in children's language abilities.

Cultural differences also dictate the accepted topics and forms of conversation. Expectations about when and how one takes the floor, who talks and to whom, acceptable and taboo topics, and the nature of skilled performance are all strongly shaped by cultural norms. When the norms at home are very different from those at school, teachers may misunderstand and reject children's contributions, leading children to feel uncertain

and potentially silenced. For example, many African American families engage in an oral storytelling tradition built around dramatic and exaggerated narratives that are organized by comparisons and themes rather than temporal sequences. Children raised in this tradition are often puzzled by teachers' efforts to elicit sequential and factual accounts, despite using language skillfully at home.

Peer and Sibling Conversations

Peers and siblings can also be conversational partners and, in some cultures, are each other's primary source of conversation. With peers, there is less scaffolding of conversations than with adults, although older children do adapt their conversation to the needs of younger children. Often these interchanges include adult conventions but require less skilled participation and allow flexible adaptation of these forms, simultaneously challenging and supporting children's performance. Children often play together, negotiate conflicts, and share ideas. More opportunities to interact with other children have been found to relate to better conversational skill, increased social perspective taking, and more effective use of conversation to manage social relationships.

Early Childhood Classrooms

Despite the interest children show in initiating conversations with parents, conversations between children and teachers are often rare. Children don't ask many questions of teachers and, in many cases, teachers are predominantly focused on managing behavior. When conversations do occur, they tend to be far more teacher-directed than children's conversations with parents. To encourage conversation and extend children's language, teachers often use open-ended questions, as well as efforts to elaborate and clarify children's contributions. These interactions can occur between a teacher and a child, or within a small group, although in groups of more than three children the reciprocal nature of the conversation is often lost.

The use of open-ended questions about topics of interest to children can support interactive and language-rich interchanges, but it is essential that teachers give children time to respond and also follow up with other questions on the same topic to extend the discussion. Teachers must also bear in mind that children may not respond to the teachers' overtures for a variety of reasons, such as uncertainty or lack of interest, and non-response should not be interpreted as reflecting a deficit in language skills without efforts to understand children's competencies at home.

The research literature on classroom conversations has focused on their role in achieving educational goals, largely children's language and conceptual development. As with parents, extended discussions of books, personal narratives, and curricular topics have all been shown to support oral language development, narrative skill, reading comprehension, and conceptual understanding. Small-group activities and center times provide opportunities for teachers to initiate such conversations. Teachers can engage children during playtime, but teachers' tendency to be directive during these conversations can limit the richness of the language and the extent of children's participation. Mealtimes have also proven to be a natural opportunity; when teachers sit with children they often converse on topics of interest to the child and use more varied and sophisticated language.

Conversation during learning activities at center times, such as science inquiries or mathematical problem solving, allows teachers to model the use of academic language and higher-order processes relevant to a particular subject, such as reviewing evidence to evaluate a prediction or justifying a process for solving a math problem. Explanations and discussions of causal relationships are frequent, providing both important information and opportunities for modeling and practicing complex language. When these conversations are child-directed, teachers can also learn about the topics that spark individual children's curiosity; curriculum driven by children's interests has proven to be one way to engage children in extended exploration of ideas in early childhood classrooms.

Conversation-Based Classroom Interventions

Efforts to train teachers to engage children in extended conversation and use elaborated language and varied vocabulary have had mixed effects. Trained teachers do not always initiate more conversations nor use more complex language, and successful efforts seem to require extensive coaching. When teachers do converse with children, positive impacts on children's oral language abilities and literacy skills have been identified. Math and science curricula that include systematic opportunities for teachers to discuss problems with individual children or small groups have also shown positive impacts on both the relevant content-knowledge and oral language skills. Although the role conversations play in children's social-emotional development has not been evaluated as extensively, there is some evidence that training teachers to engage in child-directed conversations can build a sense of connection between teachers and children. And when teachers problem solve interpersonal conflicts with children, positive impacts can also be found on children's social skills. Although not an easy skill for teachers to learn, engaging conversations can be a useful tool in early childhood classrooms.

EQUITY AND EQUALITY IN EARLY CHILDHOOD

Equity and *equality* are core constructs in moral development that describe ensuring fair, equal, and just treatment of others, and are relevant in early childhood education in terms of peer interactions as well as student–teacher interactions. Developmental science research provides clear evidence that from a very early age children recognize, identify, and reason about a wide range of transgressions as morally wrong including those involving physical and psychological harm to others, unequal treatment, and denial of rights. Further, even very young children demonstrate the capacity to act in prosocial ways, such as sharing with others and being inclusive. This entry provides an overview of moral development theory that drives research on equity and equality, reviews research findings documenting moral judgments and reasoning related to equity and equality in

early childhood and prosocial action in young children, and outlines some of the core issues surrounding equity and equality faced by children in early childhood education settings.

Overview

Research on young children's understanding of issues involving equity and equality reaches back to Jean Piaget's seminal research on moral development outlined in *The Moral Development of the Child*. More recently, Elliot Turiel proposed social domain theory as an approach that delineated issues in the moral domain, which include harm, justice, equality, fairness, and rights, from those in the societal domain, which involve customs, traditions, and conventions, and those in the psychological domain, which involve personal choice and autonomy. This model has been supported by research conducted across the life span, and in a wide array of contexts and cultures.

Broadly, findings indicate that developmentally children first recognize physical harm as wrong, followed by understanding the unfair nature of unequal distribution of resources. Following this, children evaluate psychological harm as wrong, and begin to recognize the importance of protecting the rights of others. When making moral judgments, even very young children do not just focus on the external consequences that the transgressor might experience, but reason about moral issues with a focus on intrinsic harm to others.

Research

Research on equity and equality in early childhood has focused on judgments and reasoning in children aged 2.5 years and older, while observational or behavioral research has been conducted with children who are too young to verbally justify their decisions. Research with toddlers has demonstrated very early emergence of prosocial behavior. Toddlers spontaneously aid others in distress, share with peers, and exhibit empathic concern. At the same time, young children frequently engage in conflicts with their peers. Findings indicate that as

young children develop theory of mind, the ability to recognize other's intentions, beliefs, and desires, which occurs during the preschool period, they are better able to understand that transgressions can occur accidentally. Thus, understanding others' perspectives may aid children in interpreting and resolving conflicts surrounding issues of equity and equality.

Research by Judith Smetana and colleagues indicates that most moral conflicts in early childhood, such as those surrounding equity and equality, occur between peers or siblings as opposed to with adults. Findings with preschool and early elementary school children indicate that children strongly prefer when resources are allocated equally, though they may at times act in ways more beneficial to the self. Even very young children recognize that behaviors that cause harm to others, such as inequitably dividing resources, are moral issues, and are distinct from social conventions such as procedures for lining up or customs regarding dress. Further, research documents that children recognize that behaviors such as hitting, pushing, and not sharing are morally wrong and that children prefer to hear teachers respond to such transgressions using moral language, such as appeals to ensure equitable treatment of others.

Some issues faced by young children are not completely straightforward, however. Social exclusion is a complex context for children as demonstrated by Melanie Killen and colleagues. Young children strongly reject exclusion because of the psychological harm that it causes when someone is inequitably denied entry into a group or told they cannot play with others. At the same time, even in early childhood children begin forming social groups and feel a loyalty to their group.

This conflict between group membership and a sense of equity can prove difficult for children to resolve. For instance, when children must choose between two children to include in a gender stereotypical activity (such as playing with dolls) they often justify excluding the non-stereotypical child using reasons surrounding group membership or stereotypes. Thus, research indicates the many ways in which young children exhibit an early

emerging and well-developed sense of equity and equality, while also noting that in complex or multifaceted contexts children do at times still act in inequitable or unfair ways.

Implications

Research documenting young children's early emerging sense of justice and fairness suggests many ways that early childhood classrooms can support children's development and awareness of issues surrounding equity and equality. Teachers can encourage children to consider others' perspectives when engaging in dramatic or pretend play. They can support children by ensuring that they treat all students equitably. Further, educators and parents can frame their conversations with children while considering research that indicates the importance of talking about rules and transgressions by using domain-appropriate language (for instance, discussing issues of harm and fairness for moral issues and smooth group functioning or tradition for social conventional issues).

There is often an assumption that children are selfish or incapable of sharing and acting in fair ways. Research indicates that, in fact, even toddlers reliably exhibit prosocial behavior and that very young children justify why acts such as hitting or not sharing are wrong by using moral reasons. Parents, educators, and policy makers, then, should foster positive social environments where children have opportunities to engage in social interactions and to resolve their own conflicts. Supporting children as they work together to resolve conflicts, share, and take turns can encourage children to develop strong interpersonal skills and a recognition of the core issues surrounding equity and equality.

ETHICS IN EARLY CHILDHOOD EDUCATION

This entry addresses the moral dimensions of working with young children and the role of ethics in the professional repertoire of early childhood educators. The topic of ethics was introduced to early childhood educators in 1978 with the publication of Lilian Katz and Evangeline Ward's book *Ethical Behavior in Early Childhood Education*. Since that time, professional ethics has become an important component of early childhood teachers' education in the United States. It is incorporated into accreditation standards of both programs serving young children and institutions of higher education preparing their teachers. This entry explores the role of ethics in a profession, provides an overview of terminology that relates to morality and ethics, discusses morality and ethics for educators with an emphasis on the contributions of codes of ethics, examines the National Association for the Education of Young Children's Code of Ethical Conduct, and considers what it means to be an ethical early childhood educator.

Ethics Terminology

It is helpful to begin with an overview of terminology since these terms are used in specific ways when discussing professional ethics. Following are some widely used definitions:

- *Morality*, based on personal values, is a person's view of what is right and wrong. It concerns

people's duties and obligations to one another and is characterized by words such as *right*, *ought*, *just*, and *fair*.

- *Values* are beliefs that individuals hold to be intrinsically worthwhile. They are prized for themselves and often guide behavior (e.g., truth, beauty, honesty, justice, respect). Values come from one's family, culture, community, faith, and society.
- *Ethics* involves critical reflection on moral issues. It includes the study of right and wrong, duties, and obligations.
- *Professional ethics* involves reflection on professional responsibility that is carried out collectively and systematically by the membership of a profession. Professional ethics tells professionals what they ought to do and what they ought not to do in the workplace.

Ethics and Professions

A profession is an occupation that provides an essential service and makes a commitment to promote a significant value (e.g., health, justice) that is critical to the overall well-being of society. Professionals are persons who have received specialized training and who use their skills and abilities to serve society while honoring the commitments of their profession. The degree to which an occupation is considered to be a "profession" reflects its position along a continuum that has doctors, lawyers, and similarly highly specialized occupations at one end and unskilled workers at the other. Every occupation can be thought of as occupying a position on this continuum—most fall somewhere between the two poles. Early childhood education is not considered to be a "paradigm profession," such as law and medicine, whose practitioners must complete prolonged programs of postsecondary education; whose contributions to society are unquestioned; and who are usually accorded significant pay, power, and prestige. Nor is it considered an "unskilled occupation," totally lacking specialized expertise and training. Rather, it can be regarded as an "emerging" profession. Its practitioners make important contributions to society, and the importance of the early childhood

educators' knowledge and skill is, increasingly, becoming widely recognized.

Codes of Ethics

Professionals provide a service that is essential to the well-being of their clients and to society. And because of the specialized knowledge and skill these practitioners have acquired, the society trusts them to perform their particular function. Because of this trust, members of the profession must instill confidence that they will serve the public good. They must take their responsibilities seriously and must demonstrate a strong moral commitment to do what is right and fair.

Trust in a profession is engendered through its code of ethics, a document based on the field's collective and systematic reflections about its values and responsibilities. A code sets forth the profession's moral commitments to its clients and to society. It is like a contract between society and the profession—it assures the public that professionals are acting in the best interests of their clients and are worthy of the public's confidence and support.

A profession's code of ethics provides a vision of what the profession should be like and how professionals should behave. It raises its members' awareness of ethical issues, provides guidance for ethical decision making, supports practitioners in doing what is right even if it is not easy or popular, helps those entering the field understand its commitments, assures the public that practice is based on sound and agreed-upon moral standards, and supports the best interests of those being served. Standards of ethical conduct are not statements of taste or preference. They reflect the history and values of the field, communicate with those outside the profession what they can expect from its members, and provide a shared common ground for professionals who strive to do the right thing.

Many recognized professions have a national organization to develop standards for entry, oversee the admission of candidates into membership, create and enforce ethical guidelines, investigate reports of incompetent or unethical behavior, and provide continuing education. The

study of professional ethics is an important component of most professionals' preparation.

Ethics in Education

Educational scholars agree that teaching is a profoundly moral endeavor and that it is important for teachers to understand their moral responsibilities to their students. That is why some scholars call for teacher educators to pay as much attention to teaching the ethical dimensions of teaching as they do to curriculum and instruction. But ethics has not, to date, claimed a central place in the programs of study of most preservice teacher education programs. Teachers are often left to rely on their instinctive sense of right and wrong rather than the ethical guidelines for practice applicable codes of ethics can provide.

Elementary and Secondary Education

The focus of ethics in elementary and secondary education has tended to be on the character of teachers, which is seen as having a strong impact on students' moral development, and on curriculum that directly addresses moral development in students. The most widely used moral development curricula (sometimes referred to as "values education" or "character education") are designed to shape students' sense of right and wrong and guide them toward becoming productive members of society.

There is little attention to professional ethics in the preparation of candidates preparing to teach in elementary and secondary schools. The National Council for Accreditation of Teacher Education (NCATE) accreditation has been recognized as the highest standard of excellence in teacher education for many years. Its widely relied-on teacher preparation standards include knowledge of ethical codes as a component of candidates' essential professional knowledge and professional dispositions. NCATE and the Teacher Education Accreditation Council (TEAC) were consolidated into CAEP (Council for the Accreditation of Educator Preparation) in 2013. The CAEP initial certification and advanced program standards retain the

expectation that candidates' professional knowledge includes an understanding of their field's code of professional ethics.

But while knowing and using the field's code of ethics is an essential component of the preservice curriculum for paradigm professions such as law, medicine, and engineering, instruction in professional ethics has received little attention in the curriculum of elementary and secondary preservice teachers. Two codes that could apply to teachers who work with students from preschool through Grade 12 are those developed by the American Montessori Society and the National Education Association (NEA).

The NEA Code is quite general, however, and has not been updated to reflect contemporary issues and concerns, so it is not very helpful for resolving today's ethical dilemmas, and there are few, if any, resources to help instructors integrate instruction in either of these codes into teacher preparation programs. What's more, there is still no specified place in the curriculum of most teacher preparation programs for candidates to learn about the moral dimensions of teaching and professional ethics. For these reasons, scholars continue to express concern that while there is interest in the idea of moral education, and in spite of the fact that preparing teachers for ethical practice has long been included in teacher preparation standards, there is not much emphasis on preparing teacher candidates for the moral work they will do.

Early Childhood Education

Early childhood educators perform an essential role in our society as they work with the youngest children at a critical time in the life cycle; it is therefore incumbent on them to pay particular attention to ethical behavior. In recognition of the importance of the field's moral commitments to children, families, and society, early childhood organizations throughout many parts of the English-speaking world have developed guidance for ethical decision making by adopting codes of professional ethics.

Lilian Katz and Evangeline Ward identified two characteristics of the work of early childhood

educators that underscore the essential role of ethical guidance. The most compelling reason for early childhood educators to have a code of ethics is that young children are vulnerable and lack the power to defend themselves. The adults who care for them are larger and stronger and control the valuable resources that children want and need. Young children are powerless and cannot defend themselves from teachers who are uncaring or abusive. For that reason, it is extremely important that those who work in early childhood programs act fairly and responsibly on children's behalf.

The second reason that it is essential for early childhood educators to have a code of ethics is that they serve a variety of client groups—children, families, employing agencies, and the community. Most early childhood educators would agree that their primary responsibility and loyalty is to the children. But it can be hard to keep sight of this priority when parents, agencies, or administrators ask teachers to do things that they do not think are in the best interests of children and demand that their own concerns be given priority. Early childhood educators need guidance about how to prioritize the needs of these different groups when their interests conflict.

The National Association for the Education of Young Children (NAEYC), the United States' largest and most influential professional association devoted to the care and education of young children, has mapped the ethical dimensions of early childhood education and developed its Code of Ethical Conduct to guide its members' work with young children. Another code of ethics that applies to many early childhood educators is that of the Council for Exceptional Children's Division for Early Childhood (DEC). In addition to codes developed in the United States, early childhood professional organizations in Australia, New Zealand, Singapore, and several of Canada's provinces have developed codes that reflect their local values and culture.

The NAEYC Code of Ethical Conduct

The NAEYC Code of Ethical Conduct is the best-known and most widely used code of ethics for

early childhood educators in the United States. It provides a common framework for helping early childhood educators to understand their moral commitments and offers them guidance in addressing ethical issues that arise in their work. The development of the NAEYC Code of Ethical Conduct was an important step in raising awareness of the moral and ethical dimensions of the early childhood educator's work and has provided a common framework for thinking about ethics and addressing ethical issues that arise in the work of early childhood educators. Because NAEYC is a membership organization open to all who are interested in the education of young children and not a professional association that regulates the profession, its code is not enforced.

The NAEYC Code was first adopted in 1989, after a multiyear process of development that involved extensive participation by members of NAEYC. The association reviews and revises the Code of Ethical Conduct regularly to keep it current and relevant. Members of the association were asked to provide input for revisions of the NAEYC Code in 1992, 1997, and 2005.

Organization of the Code

The NAEYC Code includes a preamble; a list of core values; four sections describing professional responsibilities to children, families, colleagues, and community and society, as well as ideals that describe how the field aspires to behave; and a statement of commitment that provides an opportunity for individuals to express their agreement with the values and responsibilities expressed in the NAEYC Code.

The *core values* articulated in the NAEYC Code reflect the central beliefs and commitments of the early childhood field and are deeply rooted in its history. They provide a foundation that makes it possible for educators to move from personal values and beliefs to a shared understanding of the professional values that apply to everyone who works with young children.

These values, set forth in the NAEYC Code, include commitments to the following:

- Appreciate childhood as a unique and valuable stage of the life cycle
- Base our work on knowledge of how children develop and learn
- Appreciate and support the bond between the child and family
- Recognize that children are best understood and supported in the context of family, culture, community, and society
- Respect the dignity, worth, and uniqueness of each individual (child, family member, and colleague)
- Respect diversity in children, families, and colleagues
- Recognize that children and adults achieve their full potential in the context of relationships that are based on trust and respect. (NAEYC, 2011)

Each of the four sections of the NAEYC Code includes a brief introduction, a list of ideals, and a list of principles. Ideals point the individual in the direction of desirable and exemplary professional behavior. The principles identify practices that are required and those that are prohibited.

Availability

The NAEYC Code of Ethical Conduct has had a strong impact on practice in early childhood education. This influence can be attributed to NAEYC's commitment to making the NAEYC Code widely available, building it into the association's activities, and making it visible to members through regular publications and conference presentations. It is available online in brochure form in English and Spanish. NAEYC has published two books about professional ethics and the use of the NAEYC Code, and an ethics column appears twice a year in the association's practitioner-focused journal, *Young Children*. The NAEYC Code is also included in most U.S. early childhood textbooks and in the curricula of early childhood teacher education programs.

Expansion of the Code's Reach

Supplements to the NAEYC Code that address the unique ethical responsibilities of adult educators

(2004) and program administrators (2006/2011) also have also been developed based on input from practitioners.

The NAEYC Code has been adopted by the National Association for Family Child Care (NAFCC) and endorsed by the Association for Childhood Education International (ACEI) and the Southern Early Childhood Association (SECA).

Addressing Ethical Issues

It is important to remember that not every issue faced by teachers of young children involves ethics. The ones with ethical dimensions have to do with right and wrong, rights and responsibilities, and human welfare. When an educator encounters a challenging issue in the workplace the first thing she or he needs to do is to determine if it involves ethics.

If it is an ethical issue, the NAEYC Code can provide guidance by first helping the early childhood educator determine if the issue is an ethical responsibility or an ethical dilemma.

Ethical responsibilities are clearly identified in the NAEYC Code. They spell out what a practitioner must or must not do, and are not subject to deliberation. The first, and most important, of the responsibilities spelled out in the NAEYC Code, and in the codes of most other professions, is to do no harm. The NAEYC Code's first principle makes this clear. P.1-1 reads, "Above all, we shall not harm children. We shall not participate in practices that are emotionally damaging, physically harmful, disrespectful, degrading, dangerous, exploitative, or intimidating to children. *This principle has precedence over all others in this Code*" (NAEYC, 2011; emphasis added). This principle tells early childhood educators that their first and most important obligation is to protect the well-being of children and that everything they do should be considered in terms of its potential to harm a child.

The NAEYC Code identifies another important ethical responsibility of teachers of young children, a responsibility shared with other professionals: to honor confidences. Early childhood educators acquire a great deal of personal information about

the children and families they serve. While it is appropriate to share children's and families' personal information with other professionals who have a legitimate need to know, communicating privileged information with others without good cause can erode trust and harms relationships.

Additional ethical responsibilities spelled out in the NAEYC Code include being aware of and basing practice on the knowledge base of early childhood education; being familiar with applicable laws and regulations; respecting families' cultures, child-rearing values, and their right to make decisions for their children; attempting to resolve concerns with coworkers and employers collegially; and assisting programs in providing a high quality of service.

Ethical Dilemmas

A very important function of a code of ethics is to provide guidance in addressing the ethical dilemmas that occur in the workplace. An ethical dilemma is a predicament that involves conflicting responsibilities; requires a choice between alternatives, each of which has some advantages, but also some disadvantages; and has more than one defensible resolution.

The following are some of the kinds of dilemmas that regularly occur in early childhood programs:

- balancing responsibilities to individual children with the needs of the other children in a group;
- navigating differences between families' wishes and teachers' professional best judgment;
- program policies, including assessment practices, that teachers believe are not in children's best interests;
- dealing with colleagues who do things that are not in children's best interests;
- concerns about colleagues' behavior including breaches of confidentiality and failure to meet their responsibilities
- observing violations of licensing or school regulations.

Deciding on the right course of action when faced with an ethical dilemma is often very difficult. Teachers can be tempted to address the issue

quickly by relying on their intuitive sense of right and wrong. It is important, however, for them to use a deliberate process to reach a thoughtful and defensible resolution based on a code of ethics as well as their good professional judgment. The first thing an early childhood educator who is using the NAEYC Code for guidance should do when facing an ethical dilemma is to determine if a child could potentially be harmed. If this is the case, priority must be given to the needs of the child.

The process described below has helped many early childhood educators decide on the most defensible resolutions to the ethical dilemmas they have encountered in their work. It is based on the second edition of *Ethics and the Early Childhood Educator* with guidance from the NAEYC Code:

Identify the conflicting responsibilities. To whom do you have responsibilities in this situation (children, families, colleagues, the community) and what do you owe to each one?

Brainstorm possible resolutions. List all of the possible ways that you might be able to resolve this dilemma.

Consider ethical finesse. Think about a way to resolve the problem that would be satisfactory to everyone involved and that would avoid having to make a difficult decision that favors one stakeholder.

Look for guidance in a code of ethics. Carefully review the ideals, principles, and core values in the NAEYC Code that relate to this situation. List the relevant items in the NAEYC Code and think about how they apply.

Decide on a justifiable course of action. Select what you think is the most ethically justifiable resolution to the dilemma. This resolution will combine guidance from the NAEYC Code with your best professional judgment. It should be consistent with your values and those of the early childhood field.

Implement, revisit, and reflect. Communicate your decision to all of those involved, taking care to respect the feelings of those who might not

have had their position supported by the decision. Consider the impact of the resolution and think about whether there are policies that could be put in place that would have been helpful in addressing it.

How can early childhood educators be confident the resolution they have reached is a good one? It can be helpful to think about the answers to these three questions: What if everyone acted this way? Could I defend this action on the evening news? Does this resolution respect relationships?

Ethical Behavior

All early childhood educators need to be aware of their moral responsibilities and know and use a code of ethics. It is equally important that they behave ethically in their day-to-day interactions. This is particularly significant because educators' role gives them power over children and families, and their behavior can have a powerful and lasting impact. Young children are vulnerable and have few defenses and resources for dealing with adults who do not treat them well or fairly. And families rely on teachers to do the right thing and to provide accurate and constructive information about their child's learning and behavior in school. For these reasons, early childhood educators must use their power and influence wisely.

Fairness means that the culture, ethnicity, gender, and abilities of children and families are respected. Ethical teachers appreciate each child as an individual, focus on strengths, and provide equal opportunities for all. They help children learn in a safe, caring, and respectful environment, and they strive to make learning interesting and meaningful.

Reflecting on the potential impact of their behavior on others helps teachers to do what is right. It is important for them to consider how children will feel about their words and to think about who will benefit from their actions.

Understanding ethical commitments and knowing an appropriate code of ethics and referring to it for guidance should be integral parts of every

early childhood educator's day-to-day practice. But a code of ethics is a useful tool only if an educator understands its contents, its spirit, and how it can contribute to professional interactions.

ETHNIC AND RACIAL IDENTITY DEVELOPMENT

Race is to a large extent a social construction of which only very little is rooted in genetics or biology. Nonetheless, race and ethnicity continue to serve as major organizing features of our society, and they play a big role in the development of one's social identity—especially for people whose racial or ethnic category is in a numerical minority. The term *ethnic and racial identity* (ERI) is commonly used to describe the process of identity development that takes place during adolescence and continues into adulthood. But this is preceded by an equally important process taking place during childhood—a process usually referred to as ethnic and racial identification. Both processes will be covered in this entry.

Ethnic and Racial Identification

Before children can identify with a particular race or ethnicity, they need to first learn what this concept entails. Children are born with an innate

ability to categorize, and this enables them to learn about the world around them. Through the various socialization practices they learn which category distinctions are important and which are not. While they easily recognize the difference between a red shirt and a blue shirt, or between a blonde and a brunette, they quickly learn that these categories are not particularly important in the social organization of our world. However, they learn that race or ethnicity is.

Around the age of 3 or 4 children begin to develop racial awareness, which means they learn to recognize racial differences, label the differences, and categorize themselves within a racial or ethnic group. The initial classification of the self is usually based on physical criteria and labels that have been discussed in the home. Between the ages of 5 and 8 children develop racial constancy, which means they understand that their race or ethnicity will not change. They also begin to show knowledge about the distinguishing characteristics of their racial or ethnic group and develop feelings about belonging to the group. This allows for more subjective identification with the group. During these early school years they also start to absorb the more complex information about racial and ethnic groups, including stereotypes and social status, but despite this, even children of minority status show very positive views of their own group by late elementary school.

Ethnic and Racial Identity (ERI)

During adolescence children begin to explore who they are, and they go through various levels of identity exploration and commitment to their choices. This identity exploration encompasses a host of issues related to their personal values, belief systems, and goals for the future. During this phase, adolescents who are part of ethnic or racial minority groups also explore how their ethnicity or race intersects with other parts of their identity and begin to make decisions about the degree to which they will adopt the values and customs of their own group and those of the majority culture. Based on Erik Erikson's theory of identity formation and James Marcia's identity

status categories, Jean Phinney identified three phases of ERI development often experienced by adolescents from minority groups. The unexamined ethnic identity (diffusion/foreclosure) phase is characterized by a lack of exploration. Adolescents in this phase may not be interested in examining their ethnicity (diffusion), or they may have stopped exploring after having internalized negative views of their ethnic or racial group (foreclosure). The ethnic identity search phase is characterized by active exploration. Adolescents in this phase are examining what their ethnicity or race means to them and the effect it has on their lives. Finally, adolescents in the ethnic identity achievement phase have developed a clear understanding and commitment to their ethnic identity.

ERI in the Context of Discrimination

Research shows that exposure to racial discrimination, or the expectation thereof, often triggers or stimulates racial identity exploration. However, identification with a minority group is not directly associated with low self-esteem. Instead, adolescents who develop a positive affiliation and pride in their ethnic group show more positive adjustments. In fact, this positive regard and affiliation with the groups is one of the main goals of ERI. The other is preparation for bias. Research on African American and Hispanic youth has documented that awareness of discrimination can buffer against some of the negative effects of discrimination and prejudice. However, this varies based on the centrality of one's ERI and the type and frequency of discrimination.

Salience of Ethnic and Racial Identity

ERI is usually studied in minority group members. One reason is that for majority group members race or ethnicity is often not very salient, and their racial group membership does not affect their lives the way it does minority group members. Similarly, race and ethnicity is not always equally salient to minority group members, because it is often situation dependent. These differences can be explained by Marilynn Brewer's theory of

optimal distinctiveness. Individuals have two specific needs, which despite their seemingly opposite objectives can be simultaneously satisfied through their social identities. One of these is the need for deindividuation, meaning a sense of belonging or connectedness to a group. The other is the need for distinctiveness, meaning a sense of uniqueness and differentiation.

By identifying with a particular group, such as a racial or ethnic group, an individual can satisfy the need for deindividuation. Simultaneously, the identification with this group also allows for distinctiveness via comparisons to other groups. For majority group members, such as White Americans, race is less salient and therefore the need for deindividuation is not easily satisfied by identifying with this majority group. Instead, they may be more likely to seek out a different social identity for this need, such as identifying as Irish American, Jewish, or College Student. Similarly, in situations where racial or ethnic minority group members are among others who are similar to them, such as a Black student attending a historically Black college, race is less salient and a different social identity may be chosen to satisfy the need for deindividuation, such as religion or political affiliation. Thus, manifestations of ERI vary across time and across contexts within individuals.

Multiracial and Multiethnic Identity

People who are biracial or multiracial are sometimes faced with the intersections of genetic, cognitive, emotional, and visual factors that contribute to their chosen identity, including what they may perceive as an imposed racial identity (what others believe they *should* identify as). Theories of ERI development within multiracial individuals can be categorized into four approaches: (1) the problem-based approach, in which multiracials are believed to be in a permanent state of crisis due to the interracial conflicts present in society; (2) the equivalent approach, in which the assumption is that multiracial individuals will identify themselves with the lower-status race, a phenomenon known as hypodescent; (3) the variant approach, which conceptualizes the multiracial population as

distinct from the single racial groups and focuses on the development of a merged biracial or multiracial identity that encompasses the characteristics of each group; and (4) the ecological approach, which posits that the multiracial identity is contextually specific—something that would align with Brewer’s theory described previously. In addition, the ecological approach also allows for a person to choose no racial identity. Most recent research shows that ERI among multiracials often changes over the life course, varies from person to person, and varies across different sociocultural contexts.

ETHNIC DIFFERENCES AND FAMILIES

The ethnic backgrounds of children in the United States are remarkably diverse, and this diversity represents rich variation in family cultures. The cultural diversity among children in early education contexts presents both challenges and opportunities for the largely monolingual and White teacher population. This entry provides examples of the ways in which young children’s home culture may differ from their early education or school setting and create opportunities for children, parents, and teachers to learn from each

other as they engage at the intersection of different cultures.

Although the number of White students enrolled in U.S. public elementary and secondary schools decreased from 2002 to 2012, children from Latino ethnic backgrounds increased considerably, according to the National Center for Education Statistics. Latino children constitute the largest and fastest-growing ethnic minority group in the United States and, by 2024, are expected to represent 29% of all students in public elementary and secondary schools. During the 2013–2014 program year in the federal Head Start program, which serves low-income children and families, 43% of participants were White, 29% were African American, and 38% were from Latino or Hispanic backgrounds. Compared to their White peers, ethnic minority children are more likely than their White peers to be living in poverty. Hence, examining ethnic group differences is complicated by the confounding of ethnic minority membership with low-income status. Finally, although data are often reported on children of color using broad racial/ethnic groupings, it is important to recognize that cultural diversity among U.S. children reflects many aspects of their backgrounds, including race and ethnicity, ancestry, immigrant or generational status, socioeconomic status, access to formal schooling, religion, customs, and home language.

Parental Goals and Expectations

In general, all parents want their child to do well, but what it means to do well differs across cultural contexts. The skills and attributes that parents think are important for their child to acquire depend on what is needed to be successful in their social context. Across cultural groups, researchers have observed variation in parents’ beliefs about goals for their children, when children should acquire specific skills, the roles parents and other adults should play in children’s development, and how children should behave with peers and adults. When parents’ beliefs and values differ from those of their child’s teacher, the ease with which children transition between the cultural contexts of home and early learning center (or school) may be hindered.

Although acknowledging that within all cultures there are dimensions of both independence and interdependence, social scientists have argued that an important way in which cultures differ is in their emphasis on individualism and independence versus an emphasis on collectivism and interdependence. Researchers such as Robin Harwood have argued that having a stronger cultural emphasis on autonomy versus interdependence leads to differences in how parents socialize their child. For example, in a classic study of the goals and expectations of Puerto Rican and Anglo mothers, the Anglo mothers were more likely than Puerto Rican mothers to focus on their young child's personal development. They wanted their child to become independent and confident and to develop his or her own particular abilities and interests. In contrast, the Puerto Rican mothers were more likely to stress the importance of having a child be respectful, affectionate, and loving. This difference in emphasis between becoming independent and developing strong relationships with others is thought to reflect the broader cultural orientations toward individualism versus interdependence. European American mothers who want their toddler to become autonomous are more likely to expect their child to be able to play by herself in another part of the room if the parent is talking with another adult and not to cling to the parent. On the other hand, the Puerto Rican mother might expect her child to sit close by her while she visits with someone else. These two perspectives can lead parents to have different expectations of what is "normal" for a child who enters a preschool classroom for the first time. One mother might be happy for her child to quickly engage in some activity in the room. Another might be disappointed if the child did not cling to her for a while.

Parents' general knowledge of child development and expectations for when children attain developmental milestones varies across groups. Sometimes these differences are related to scientific knowledge about children's development. For example, researchers have found that compared to U.S.-born middle-class parents, middle-class immigrant parents were less likely to know when infants

attained certain physical milestones, such as being able to lift their head up when lying on their stomach or how much time a typical newborn cries during a day. Such differences may present opportunities for early childhood educators to provide information on child development to parents. Other times, these differences reflect cultural beliefs about the development of parent-child relationships. In a study of mothers with 8-month-old infants, researchers found that on average middle-class Anglo mothers expected infants to begin to feed themselves around 10 months of age and to master self-feeding between 18 and 19 months. In contrast, middle-class Puerto Rican mothers thought their infant would begin to self-feed around 17 months of age and to master self-feeding around 24 months. One can easily imagine that this difference in expectations might lead to young children in a toddler class having more or less comfort with self-feeding at snack time.

Parent Engagement in Children's Early Learning and Schooling

As a function of their beliefs and perspectives on early development and education, parents differ in the learning experiences they provide their children both inside and outside the home. For example, in a nationally representative sample of families in the United States, European American parents report reading more frequently to infants compared to Asian American, African American, and Latino parents and are more likely to read to preschool-age children than African American and Latino parents, but not Asian American parents. Similarly, European American and Asian American parents are more likely to teach their children numbers and shapes than are African American and Latino parents.

Differences in the types of early literacy opportunities that parents engage in with their children have been associated with differences in parents' beliefs about how and when children learn to read. For instance, in Latino immigrant families, parents are less likely to share books at home with their child until the child has learned how to read in school. The Latino immigrant parents generally do

not view emergent literacy behaviors as meaningful learning activities, and thus do not read to their child until they perceive their child to be capable of understanding a story, usually around the age of 5. Further, when reading to children, Latino immigrant parents are less likely to engage in academically oriented interactions with their child, such as asking questions about the story or giving explanations of concepts that are connected to the story. The Latino immigrant parents believe that there are other ways in which parents prepare their children for school. To help children do well in school, Latino immigrant parents report teaching children to obey and to learn right from wrong. They stress the importance of telling children stories in order to convey moral content. Such factors may be one reason that Latino children from Mexican American backgrounds evidence strong social development outcomes in early childhood but weaker language and academic outcomes in comparison to their monolingual peers and Chinese immigrant families.

Across ethnic and cultural groups, parents tend to approach childrearing in different ways, particularly with respect to levels of parental warmth and control. Considerable research has examined cultural influences on practices related to parenting style, conceived as the stress parents place on nurturing and granting autonomy to (or exercising control of) their children. In general, research on parenting style has found that parents who are warm and nurturing and who set appropriate rules for their children (i.e., parents who have an authoritative parenting style) have children with higher academic achievement compared to parents who are either too strict or too lenient in their parenting.

Although positive effects of authoritative parenting are found for European American parents, the relation between authoritative parenting and school achievement is not consistent across families from other ethnic and socioeconomic backgrounds. For example, studies of first-generation Chinese parents have found parents to be highly controlling and yet to have children who perform remarkably well academically. Similarly, compared

to European American parents, low-income African American parents are more likely to elicit control and fear in their children, and this behavior is associated with positive outcomes related to children's safety and schooling. Among Latino mothers, researchers have observed that parents' use of directive or high power assertion strategies are associated with generational status (first- versus second-generation immigrant) and maternal education. Mothers with more education, and who are less likely to be first-generation immigrants, use more inductive strategies than mothers with less education and those who have recently immigrated to the United States.

Research examining ethnic minority mothers' home learning behaviors reveals differences in book sharing styles of African American, Dominican American, Mexican American, and Chinese American mothers from low-income backgrounds when sharing a wordless picture book with their child. African American and Mexican American mothers were more likely to have discussions about story components during book sharing than were Chinese mothers. Compared to other mothers, African American mothers talked more frequently about the characters' individual goals; Chinese mothers were least likely to refer to individual goals. However, Chinese mothers made more references to negative consequences of actions compared to other mothers. Dominican and Mexican American mothers talked more about the emotions of the characters compared to other mothers. These findings appear to highlight cultural differences in parents' beliefs about children's development.

Although differences appear to exist between mothers from various cultural backgrounds, it is important to note that larger differences are often evident in book sharing and teaching styles between parents with less education (or lower socioeconomic status) and those with more education within a given cultural group. Parents with less education are more likely to approach and view their children's literacy development as a discrete set of skills that children need to acquire. As a result of these beliefs, parents with less education

are more likely to emphasize the importance of providing direct instruction in basic literacy skills (e.g., teaching children the alphabet) in order to help children learn to read.

In contrast, parents with more education are more likely to consider a wider range of language, reading, and writing activities to foster children's literacy development and to embed such activities within regular family routines. These parents are more likely to facilitate children's involvement with reading and writing activities by making learning to read fun and enjoyable for children, and using social interactions and language in ways that foster children's motivation for reading (e.g., cooking with a recipe card or reading signs at a grocery store). Importantly, differences in the home literacy experiences of children in low- and middle-SES homes have been observed in multiple ethnic groups. Because parents with different backgrounds may use different literacy strategies with their child, it is important that early childhood educators encourage multiple ways for parents to promote children's language and literacy skills rather than, for example, one prescribed manner of reading a book.

Finally, given the diversity in the United States, many early childhood educators have classes comprised of children who represent a variety of cultural backgrounds. Although this entry has provided a few examples of the ways in which cultural groups differ, it is likely impossible for teachers to be familiar with the cultural values and practices of all of the families they touch. Moreover, within any particular ethnic or racial group, there is much diversity. Among Native American families, for example, there is no one set of beliefs and values that is embraced by all Native American families. The same is true for other groups. General knowledge about a racial or ethnic group does not necessarily apply to a specific family from that group but may help early childhood educators understand why some children and parents act in ways that do not conform to the teacher's expectations.

EXECUTIVE FUNCTIONING

Executive functioning skills, as opposed to academic skills, are often called soft skills or character traits of learners. These soft skills have been shown to be essential, perhaps even more important than native intelligence, for academic success through the school years and are also related to adult success in the workforce and as family members.

Executive functioning consists of the following four skills:

- Working memory: Ability to hold information and recall it when necessary
- Cognitive flexibility: Ability to change tasks, multitask, and adjust mental effort
- Inhibitory control: Ability to resist distractions no matter how compelling
- Self-regulation/self-control: Ability to inhibit a dominant response in favor of a less salient one, ability to delay gratification

The skills are described in more detail as follows:

Working memory is the ability to retain information and to call on that memory when needed and is acknowledged for building a child's knowledge without rote memorization. As a child has more and more experiences, more and more memories are stored. For early literacy development, vocabulary, decoding, and comprehension all utilize working memory. Working memory helps in making decisions between two or more choices in order to determine the most desirable or logical response to an action or situation. Taking the perspective of others is another key factor of working memory. Related to perspective-taking, working memory is required for metacognition—the ability to reflect on one's own thoughts.

Cognitive flexibility allows the brain to switch thoughts and to hold two or more thoughts simultaneously, necessary skills for multitasking. Cognitive flexibility is also the ability of the brain to adjust mental effort according to the difficulty of the task, such that harder tasks get more time

and easier tasks may require no mental effort at all. The brain's capacity to exert more effort on unfamiliar tasks and concepts allows a learner to filter through familiar or everyday information in search of more complex information. This ability to allocate more or less attention depending on the difficulty of the task allows for more efficient and appropriate work.

Inhibitory control is perhaps the most essential skill in the suite of executive functioning skills; it is the ability to resist distractions and stay on task. One could argue that this skill is even more important than native intelligence for success in school and life. Lacking the ability to prioritize and focus on one specific goal at a time significantly lowers the probability of success in completing tasks that are necessary for meeting goals. All successful learners have a healthy amount of inhibitory control.

Self-regulation is defined as self-control, or the ability to suppress emotions, feelings, or wants in order to complete a task or follow instructions. People often refer to the so-called marshmallow test when describing children who have or do not have this skill of self-regulation. In this test, children from the ages of 3 to 6 years old are presented with one marshmallow on a plate. The child is told that he or she can eat the one marshmallow now, or if the child can wait until the researcher returns (15 minutes later), the child will get two marshmallows. Some children eat the treat right away, some nibble at little pieces and/or lick the marshmallow, but some children can wait the full 15 minutes using a variety of strategies to thwart the eating of the marshmallow. Young children who are able to wait until the researcher returns are exhibiting self-control and demonstrating well-developed skills related to executive functioning. Delaying gratification is an essential skill in just about everything successful individuals do. Interestingly, the original marshmallow test study was longitudinal and showed that those children with higher levels of executive functioning scored significantly higher on the SAT than did those with lower executive functioning ability.

An additional aspect of both self-regulation and inhibitory control is emotional regulation. The ability to momentarily suppress and control our emotions in order to accomplish a task is an especially important skill for student–adult, student–peer, and adult–adult relationships.

Brain research using MRI shows that the primary home of executive functioning skills is the prefrontal cortex of the brain. Brain MRIs of children identified as having high levels of executive functioning show extreme activity in the prefrontal cortex of the brain. Children with lower executive functioning skills show a much lesser degree of activity. Research on the positive relationship of middle school reading comprehension and executive functioning skills, again demonstrated with MRIs of the brain, is quite clear. Middle-schoolers who have high levels of reading comprehension also have MRIs showing a high level of activity in the prefrontal cortex, home of executive functioning.

Finally, two analogies can illustrate what executive functioning skills do in the big picture. The first analogy is to think about the way an executive of a successful company or business manages his or her people and business. This high-level executive is fully aware of all that is happening in the company and uses information from multiple sources. The executive has a vision of where he or she wants the company to go. The executive is motivated internally and can motivate others.

The second analogy is that our executive functioning ability is like the ability of an air-traffic controller (ATC). The prefrontal cortex of the brain takes in all the incoming data as the ATC does with multiple incoming airplanes: multiple speed/level, and wind direction data, and changing weather information. The ATC brain ignores what is not immediately most important. The ATC uses past knowledge to make the correct decision for information at the present moment. The ATC has self-control and can ignore the fact that he or she may have had an argument with his or her spouse before reporting for duty. Finally, the ATC is flexible if more information becomes available, changes, and/or is more complex, requiring greater effort.

Executive function develops rapidly from birth to 8 years of age. Sociodramatic or pretend play with others requires a child to use working memory, flexibility, inhibitory control, and self-control and is the primary means of developing executive functioning.

EXPRESSIVE LANGUAGE

Expressive language refers to the ways in which human beings use language to communicate their thoughts and feelings. Children's expressive oral language skills are related to their overall language and literacy learning, their academic success, and their socioemotional development. Competence in expressive language has strong implications for children's sense of self, as well as for their relationships with others. This entry provides an overview of expressive language, with an emphasis on issues related to its significance, the process of developing expressive language, and

recommendations for practices that support expressive language in children.

The Significance of Expressive Language Development

Language is one of the most significant elements of human life. While debates have raged regarding the exact nature of oral language and its development, few would question its power and impact, nor the fact that the ability to use language distinguishes people from other living creatures and plays a defining role in what makes us uniquely human.

In broad terms, language is typically classified as being receptive or expressive in nature. Receptive language is a general term related to language input. It refers to the ways in which children hear and interpret the language that surrounds them. Conversely, expressive language is related to the concept of language output—the way in which children use language in order to communicate with others. Although these terms appear to indicate opposite aspects of language, it should be noted that the two processes are both inextricably linked and reciprocal in nature. Receptive language strongly impacts expressive language development, and vice versa.

The development of expressive language is crucial for children for many reasons. In brief, expressive language competence significantly impacts children's overall ability to communicate, to form social bonds, and to make academic progress in literacy, as well as across other areas of the curriculum.

Communication

Expressive language is a powerful communication tool that actually begins in a prelingual phase. Even before infants are making conscious use of language, they are able to cry, vocalize, and capture the attention of others. As they mature, children gain greater control over the sounds of language, begin to form words, and can eventually share desires, make observations, pose questions, and tell stories. They learn to express themselves from both a personal (“Love doggie!”) and more objective (“It’s a dog.”) perspective.

Most significantly, children use expressive language as a means of interacting with others. They learn that this type of self-expression incorporates verbal and nonverbal communication skills, involves turn-taking, and requires them to use their receptive language skills to better understand what is being shared by others. They engage in increasingly complex conversations, eventually learning the social mores and tacit rules that govern different types of communication. As they converse regularly, children gain confidence in their abilities to express themselves and to use language to communicate in authentic ways across varied contexts.

Social Bonds

Language is a uniquely social phenomenon. As children develop linguistic skills, they not only learn to express themselves, but they also find an important avenue through which they can connect with other human beings in important, authentic ways. Communication with others brings the expectation of a response. Thus, expressive language allows children to interact; to make themselves known, and in turn, to be known by others. In this sense, expressive language serves as a springboard for forging social bonds and as a means for nurturing these relationships.

Because expressive language is such a powerful relational tool, it plays a crucial role in children's social-emotional development and well-being. Children who struggle to express themselves may find it difficult to initiate new relationships and to connect meaningfully with the important peers and adults who are already in their lives. An inability to express oneself can result in social isolation and, in turn, can lead to sadness, frustration, and related negative, aggressive behaviors. This cycle can then lead to further misunderstandings and isolation. Conversely, children with strong expressive language skills are able to communicate more effectively, making it easier to establish friendships with peers and deepen relationships with family members, teachers, and other caring adults.

Academic Progress

The ability to effectively use expressive language is predictive of children's later literacy learning and overall academic success. There are strong connections between oral and written language competence. Thus, children who have strong speaking and listening skills also tend to develop strong reading and writing skills. As children utilize their expressive language skills, they not only learn more about language, but they also are able to use language to learn in more effective ways. This factor can positively impact their engagement and success across every area of the curriculum.

The Development of Expressive Language

Language acquisition, the way in which children acquire, learn, and develop language, plays a central role in children's overall development. This process of expressive language development is complex. It has been explored and debated by a wide range of scholars.

Theoretical Foundations

Many theorists have considered the ways in which the roots of expressive language are situated on the nature–nurture continuum. At one end of the spectrum, behaviorists, in the tradition of B. F. Skinner, emphasize the centrality of the nurture aspect. Expressive language development is viewed as a process strongly influenced by external factors and which evolves through ongoing imitation, stimulus–response learning, and the reinforcement of behaviors. At the other end of the spectrum, innatists, such as Noam Chomsky, emphasize the role of nature. Adherents to this perspective believe that children learn to express themselves primarily because language is an innately human ability and because they are biologically wired to communicate.

Theorists have also explored the role of constructivism, which emphasizes children's active sense-making processes in the development of expressive language. Jean Piaget's work is associated with models of cognitive constructivism.

This perspective posits that children's thinking leads language development and that children learn language by actively testing linguistic hypotheses in everyday speech. Expressive language is viewed as a reflection of cognitive knowledge. In contrast, Lev Vygotsky's work is based on the concept of social constructivism. From this perspective, children learn expressive language through active engagement within a social context, with an emphasis placed on the special role that interactions with adults and more experienced peers play in the facilitation of children's talk. Social constructivists believe that language not only reflects cognitive learning, but also leads it.

Although there are many different perspectives on the way expressive language develops, it is clear that it is a complex process deeply impacted by both internal and external factors. Expressive language development has a strong biological component and is also greatly influenced by environmental factors and early learning experiences. Children are active meaning makers who are influenced strongly by both cognitive development and the authentic social opportunities for using language that surround them.

Language Development

Expressive language development begins in the child's prelinguistic stage. Through the use of vegetative sounds, crying, cooing, and other forms of vocal play, babies begin to communicate with others. With time, typically developing children move into more formalized language. During the first year of life, they babble, approximate sounds, and begin to imitate words. Eventually, they communicate in one- and two-word utterances, which give way to simple sentences, and then narratives. Over time, children develop enhanced vocabularies, refined pronunciation, and a growing control over the core systems of language, including semantics (meaning), syntax (word order and sentence structure), grapho-phonics (sound-letter associations), and pragmatics (using language in a contextually appropriate manner), allowing them to express themselves effectively.

Recommended Practices to Support Expressive Language Development

There are many ways to support children's expressive language development. Primarily, expressive competence emerges through immersion and involvement in supportive, language-rich environments. Since early childhood is the key period for language development, it is crucial that parents and caregivers understand the importance of actively involving children in authentic language experiences from their earliest days. This involves surrounding babies with caring talk and immersing them in conversations even prior to the time when the child demonstrates any type of linguistic understanding. Responding to the child's vocalizations helps to provide a sense of reassurance, demonstrating that self-expression invites a response and is thus a powerful, shaping force on daily life. The use of gestures, facial expression, and parentese (an exaggerated form of speech used by parents and caregivers with young children) all help to scaffold and encourage expressive language.

Research indicates that daily life experiences that invite conversation provide an excellent means to enhance children's expressive language development. For example, family mealtimes offer a forum for children to actively participate in conversations covering a range of topics such as daily activities, different types of food preparation, current events, and family traditions. In this setting, children have an opportunity to engage sophisticated topics while trying out new vocabulary and conversational styles in a safe, supportive setting. Likewise, engagement in bedtime stories provides children with models of expressive, effective reading that they can use as they tell stories of their own. Opportunities to ask questions and make comments within the read-aloud frame invite the use of language in meaningful ways.

Early educators can utilize similar strategies for supporting expressive language. Children benefit from language-rich learning environments in which there are many opportunities to engage in meaningful talk with both peers and adults. This can be facilitated first and foremost by creating a

classroom culture in which every member feels valued, supported, and safe when sharing with others. Teachers can further enhance language learning by organizing classroom seating in small-group settings that make conversations seem natural and easy, by encouraging children to converse over snacks and meals, and by providing multiple opportunities for children to articulate their learning and express thoughts and feelings throughout the day. Morning meetings and other sharing times can be effective forums for the development and authentic use of expressive language. Socio-dramatic play offers an especially rich opportunity for children to use varied types of language within a safe, engaging setting.

As at home, school-based interactive read-alouds and related discussions offer abundant possibilities to both hear and use different forms of language. Songs, chants, and musical games can all serve as opportunities for children to use expressive language in joyful, contextualized ways. Teachers can further support expressive language through key pedagogical strategies that allow children to use and practice language. For example, think-pair-share activities provide a means for intentionally connecting thought and language and offer an opportunity for children to express their thoughts through a process of graduated risk: They first engage in self-talk, then talk with an audience of one, and then finally share with the full group. Some children may benefit from practicing social scripts, as in the "greeting game" or "compliment game," which provide opportunities to brainstorm and practice common, effective communication exchanges.

Finally, educators should be aware of general language development benchmarks and be alert to children's progress with them. Children who struggle with expressive language may need more targeted support. In many cases, children who exhibit language delays or disorders would benefit from the services of a speech-language therapist.

FAMILY CHILD CARE

Family child care is out-of-home paid care that is provided to a small group of unrelated children age 6 years or younger in a private residential home. The definition of family child care does not extend to unregulated, informal, or short-term care provided by a related family member, friend, or neighbor. In general, family child care homes provide care to six or fewer children age 6 years or younger. Large family child care homes, however, can serve up to 12 children and may employ additional staff to ensure that appropriate ratios are maintained. The maximum number of children served in a home-based setting varies by the age of the children and from state to state. This entry identifies the key characteristics of family child care and its potential effect on children's development. A summary of current research on topics of special interest to the area of family child care is also presented.

Overview

In the United States, parents of young children have three primary types of out-of-home care from which to choose: center-based child care, where children are grouped by age in classrooms (similar to school settings); family child care, where children are in a small mixed-age group environment; and nanny care, where one or two children are looked after in their own home.

An analysis of 1985 to 2011 U.S. Census Bureau data by Child Trends in 2013 indicates that approximately 14% of children attending some type of child care arrangement are in family child care homes. This number is expected to decline over time as the availability of center-based care increases. The unique home-like atmosphere and smaller group sizes generally evident in family child care make it a primary choice for many parents of infants and toddlers. Parents with more than one child, low-income parents, and single mothers are also more likely to use family child care than any other care option. Compared to families who choose center-based care, families who use family child care report more satisfaction with the type and quality of care provided. They describe it as available, affordable, and flexible to their needs.

Advantages of Family Child Care

Studies show that there can be a range of advantages to family child care. The type of intimate care provided in a family "home away from home" setting, for example, can offer a sense of safety and belonging for children and parents; unlike a center-based environment, children do not have to move to a new classroom when they achieve a particular developmental milestone or when they reach a birthday, and parents and children do not have to adjust to a new teacher each time a move is made. Since secure and continuous relationships

are demonstrated by research to provide the foundation for young children's healthy social and emotional development, family child care settings can be uniquely placed to nurture children's feelings of trust, comfort, and attachment. Moreover, when compared with center-based care where group sizes are often large, the small groups in a family child care home can seem less institutional.

An additional aspect of family child care that may present advantages is the natural opportunity for children to play with and learn from peers of various ages. Home-based child care closely matches heterogeneous family-like relationships. In this environment, younger children are more likely to be exposed to the complex language and play of their older peers, while older children can strengthen their knowledge and learning by teaching new skills to their younger counterparts.

Family child care settings also offer opportunities for children to develop and practice social skills. Children learn to differentiate their expectations as they interact and mix with peers of various ages whose development can fluctuate substantially. The mixed-age grouping invites children to learn skills such as patience, compassion, problem solving, negotiation, and compromise. Unlike in the more uniform structure of a child care center, children in a family child care setting are not grouped according to birth date; therefore, chronological age is less likely to become the single determinant of children's developmental level. Children have greater freedom to develop at their own pace. The caregiver (or provider) gets to know each child individually and is generally more accepting and tolerant of a greater diversity of maturity and performance. This factor may benefit at-risk children with behavioral or other challenges. In a small-group environment, children with developmental difficulties may receive more individualized attention and have opportunities to learn appropriate social and other skills in a noncompetitive way.

The Research Base on Family Child Care

All states regulate family child care. Individual states determine many aspects of family child care

functioning, including (a) whether homes are registered, licensed, and/or inspected to ensure that basic health and safety prerequisites are in place; (b) the number of unrelated children allowed to be cared for in the home environment; (c) the type and nature of professional development—from initial training (preservice) to annual training (in-service)—required of providers and staff; and (d) whether children are exposed to appropriate early learning experiences. These variances in conditions make evaluating the impact of family child care homes on children's healthy development and learning a somewhat challenging task. As a result, the majority of research investigating the impact of quality in the past has focused on licensed child care centers.

In recent years, however, attention has turned to examining the quality of family child care homes in detail. Outcome data from observational and standardized measures suggest that when compared with child care centers, family child care providers often do not provide the type and quality of experience that promotes young children's optimal growth and learning. Children who attend child care centers score higher on measures of language and cognitive development than those in home-based child care. Children who attend high-quality family child care score higher on measures of language development and displayed fewer behavioral problems than children who attend lower-quality family child care homes.

With regard to ethnicity, a study of Head Start family child care reported that the lowest-quality care was found in programs serving African American children; programs serving largely Hispanic children were of lower quality than those serving largely White children. Overall, only a small portion of family child care programs have been found to be of good quality; the majority provide mediocre or inadequate quality care.

The reason for this disparity in quality is multifaceted but may include the following:

Educational Level. There is an association between the level of general education and specialized professional development received by providers and quality of programming in family child care; more

education and professional development results in higher scores on global measures of quality and better outcomes for children. Providers in home-based settings often have significantly less formal education and fewer hours of ongoing professional development than child care center teachers. As a result, aspects of quality such as the richness of the learning environment and caregiver attention, responsiveness, and sensitivity can be negatively impacted. Children who attend programs where caregivers are not emotionally supportive or warm score lower on tests of language and cognitive development than their peers who attend programs with caregivers who presented with higher levels of sensitivity. These scores are not mediated by family income level.

Feelings of Isolation. Family child care providers are more likely to be caring for children in their own home. They work alone and play multiple roles throughout the day. As a result, providers do not consistently experience the type of performance-improving feedback and support from peers, supervisors, mentors, or coaches that teachers in other settings receive. This lack of a social network can create feelings of isolation and can contribute to provider stress. Providers who have access to support services in the form of a family child care association or a similar organization are more sensitive and responsive to children's needs and score higher on measures of quality.

Attitude and Commitment. The level of dedication to the field of early care and education has been demonstrated to predict higher-quality family child care programming. Those providers who genuinely like working with children and who take a professional approach to their role are more likely to feel satisfied with their career choice. They are more likely to seek and access professional learning opportunities, plan and implement appropriate curriculum, and find other providers. A positive attitude and commitment to the field of early care and education influences family child care provider interactions with children. Stress and turnover are reduced.

Regulation by Outside Agencies. Many states fail to require the same elements of program quality such as developmentally appropriate principles and best practice in early childhood education that are mandatory in center-based care. When standards are not explicitly expected, quality curriculum can, at best, be left to chance.

Conclusion

The impact of low-quality family child care learning environments can be long-lasting. While family child care is distinguished from other forms of out-of-home care in that it supports small, intimate, multi-age groupings, the quest for quality remains an elusive ideal in many settings. Initiatives by policy makers, child care managers, family child care administrators, and others need to venture beyond examining or regulating basic criteria such as licensing and qualifications. It is vital for children's optimal growth and development that they receive high-quality experiences and interactions throughout the day, regardless of the type of early care and education setting.

Indeed, consistent with the type of standards expected in regulated child care centers, family child care programs should demonstrate that a daily schedule and planned learning activities in the form of a curriculum plan are evident and implemented. Schedules should be responsive to children's needs, a daunting task when a diverse range of ages must be considered and accommodated. Curriculum activities should provide appropriate stimulation and be aligned with evidence-based learning objectives. Most essentially, provider-child interactions must be positive. Positive interactions have been demonstrated by research to provide a secure foundation on which future learning is built. Finally, the family child care learning environment must at all times meet (and, if possible, strive to exceed) the highest standards of safety and health.

FAMILY ENGAGEMENT IN CURRICULUM

Family engagement, or the myriad ways in which parents support their children's education, is a multidimensional construct that encompasses parents' activities at home, at school, and in the community. Family engagement has been linked to both academic and social-emotional outcomes for students across grade level, racial/ethnic group, and community type. Moreover, benefits of family engagement during the preschool and early elementary school years appear to have long-lasting effects, linking to positive outcomes in high school and early adulthood. Research suggests that promoting positive family engagement early in children's education might help address achievement disparities between low- and middle-income children and between dominant and nondominant ethnic groups. For this reason, programs like Head Start, the largest federally funded early childhood intervention program serving low-income, ethnically and linguistically diverse families with young children, have prioritized family engagement within their core mission (e.g., H.R. 1429; U.S. Department of Health and Human Services, 2007). However, the question of what counts as meaningful engagement among socio-culturally diverse families and what family engagement supports are most effective remains an important question.

During the early childhood years, home-based engagement activities might include helping children develop pre-academic skills (such as counting and recognizing the alphabet), creating a space for them to engage in learning activities at home, taking them to places in the community to learn (e.g., museums, the library), and reading to them. School-based engagement typically includes activities such as attending parent-teacher conferences, having regular forms of communication with the teacher, or volunteering in the classroom. Parents who are involved in their children's education both at home and at school in these ways have children who demonstrate greater levels of academic success, such as better school attendance, higher levels of

motivation toward learning, greater social competence, and overall higher academic performance, including reading and math achievement. It is hypothesized that through these types of participation in children's schooling, families socialize their children to value achievement by modeling and reinforcing pro-academic behaviors. For example, when parents engage in educational activities with their children at home, they communicate clear expectations for achievement and often integrate school curriculum goals within home routines. A second hypothesized pathway through which family engagement may support children's school success is by promoting positive affect and self-efficacy for achievement.

Although research has acknowledged the multidimensionality of family engagement, most studies continue to focus primarily on school-based participation. One explanation for the predominant focus on facilitating school-based participation is that through school contact, parents gain valuable information about how to engage their children at home; thus, school contact serves as a precursor to home-based engagement. However, for many low-income, ethnic minority and immigrant families, educational, cultural, and language divides likely lead to a preference for home-based engagement, which might manifest in culturally specific educational involvement behaviors that remain largely unaccounted for and invisible. Though there may be great value in the kinds of school-based activities typically represented in family-school connections research, what some scholars are calling for is greater understanding of the ways in which these activities are also relationally situated. They have pointed to the need for research concerning *co-determined* activities and those that reflect the notion of shared responsibility among educators and families, as well as more research on constructs such as *joint engagement* between teachers and parents. This fundamental shift to a relational approach brings into focus the need for a radically different orientation toward the issue of family-school connections, as well as the need to reconceptualize current delivery models of family engagement programming. Family engagement in early childhood curriculum, the topic of focus

here, represents one potential avenue by which the relationship between families and teachers may be enhanced and leveraged to foster culturally relevant curriculum in the classroom.

Family Literacy as an Approach to Engaging Families in Curriculum

Pioneering work in family literacy was conducted in the 1980s to develop a two-generation strategy to support children who were living in poverty and who had parents with low levels of literacy. Family literacy programs include literacy-rich programs for young children, literacy development and education services for parents, and interactive literacy activities involving both parents and their children. A large body of research has demonstrated that such programs can result in positive effects on children's language and literacy development. For example, family literacy programs may change the way parents interact with their children's preliteracy development by helping them tell richer stories or by repeating and expanding on their child's utterances in everyday conversations. In addition, research has shown that literacy is an area of curriculum where schools can meaningfully engage parents by facilitating activities that connect children's in-school and out-of-school experiences. Immigrant parents have been especially encouraged to participate in these programs in order to gain literacy skills in English and perhaps their home language, as well as to acquire navigation strategies that can increase their access to resources to foster their children's learning.

For example, Ada and Campoy created a program, called *Authors in the Classroom*, to invite students, family members, and teachers at all grade levels to share their ideas and cultural stories through poems, stories, photo essays, and books. Teachers encouraged family members to write in their home language; if parents did not feel comfortable writing, their children helped them write stories or tape-recorded them, so that children could hear their own parents' voices in the classroom. This program facilitated a way for immigrant families to be a part of the children's learning

community while not having to be physically present. Their stories became classroom books with contributions from all children and families. Furthermore, this program helped teachers foster dialogues with their students and families that helped build meaningful relationships with families from a variety of cultural heritages.

Another example is the Home School Knowledge Exchange (HSKE) project, through which an effective two-way communication between home and school was developed and implemented. As part of the HSKE project, teachers sent children home with an empty shoebox. Parents were encouraged to work with their children to decorate the box and fill it with items that were special to them (e.g., photos, writing, postcards). After the shoeboxes were returned to school, teachers incorporated children's unique home cultures and personal stories across the curriculum via creative writing, observational drawing, and student presentations. For example, children took turns presenting to the class why they had chosen particular artifacts. Teachers then encouraged children to use their artifacts in their writing and drawing collaboratively with peers. Their completed work was word-processed, spiral bound, and became their own personal books, which then were sent home to be shared with their parents. This activity allowed students to bring aspects of their home lives into school, and allowed teachers to become more knowledgeable about children's out-of-school interests and home cultures, incorporating them into the formal curriculum.

Family Funds of Knowledge

Teachers' efforts to engage families in early childhood curriculum have also been highly influenced by the work of Luis Moll and colleagues, who coined the concept "family funds of knowledge." Family funds of knowledge are defined by Moll and his colleagues as "[the] historically accumulated and culturally developed bodies of knowledge and skills essential for household or individual functioning and well-being" (p. 133). Essentially, students' families' funds of

knowledge are viewed as valuable resources to help teachers better understand children's lived experiences and develop culturally relevant curriculum. The following hypothesized pathway has been posited: When teachers link new information to students' prior knowledge, experience, and home and family activities, they motivate students' interest and curiosity, imbuing the classroom curriculum with a sense of purpose. This particular work challenges expectations about traditional forms of family engagement and delineates various ways by which teachers can become ethnographers to learn about children's homes, cultures, and communities in order to reflect this knowledge in their classroom curriculum. Moll, Amanti, Neff, and González view children's households as "containing ample cultural and cognitive resources with great, potential utility for classroom instruction" (2005, p. 75). Therefore, the concept of family funds of knowledge enables teachers to move away from "thin" and "single-stranded" relationships with children and their families and helps them to create a culture-sensitive curriculum.

As an example of researchers and teachers attempting to access families' funds of knowledge, Norma González and her colleagues collaborated with teachers to visit families' homes in order to have open conversations, learn routine household activities, and listen to parents' views of their roles in children's learning. The study emphasized the importance of building trust with families and highlighted that teachers can play a critical role as a bridge between the students' out-of-school lives and the classroom experience. More recently, applying a funds-of-knowledge approach, Gregg, Rugg, and Stoneman presented their *Míreme* [Take a Look at Me] project. In this project, researchers initiated focus groups with Latino families to encourage reciprocal dialogue between teachers and families. The project underscored the importance of listening to the voices of families (e.g., their unique culture, familial background, resources, insights, strategies) by placing teachers (rather than parents) as the recipients of information. Both of these studies underscored the importance of home-school communication in order to

bridge the gap between teachers and parents and, more importantly, encourage teachers to look at families' funds of knowledge as legitimate sources of information for building curriculum.

Parents as Co-Teachers/Co-Educators

Studies have also documented the benefits of teachers co-teaching with parents, an activity that encourages teachers to come to view parents as equal partners and leaders in their children's education. Most recently, Tazi, Gunning, and Marrero implemented a pilot program that incorporated parents as co-teachers to support young children's STEM (science, technology, engineering, and mathematics) learning. The Parents-as-Coteachers Program included two evening sessions that exposed parents to the process of facilitating a child's STEM learning. In these two sessions, parents and teachers discussed the four disciplines of STEM and teachers modeled an activity that parents could do at home with their children. Parents reported seeing the value and responsibility of co-teaching STEM subjects to their children, as well as reported having learned the importance of satisfying children's curiosity in order to enhance STEM learning.

Taking this notion of parents as co-teachers a step further, in a study by Loizos Symeou, teachers invited parents into the classroom to co-create children's learning activities, to co-develop a set of guidelines for parents' participation, and then to co-teach in the classroom. Through surveys and in-depth interviews with parents and children, the findings showed how relationships among teachers, parents, and children were enhanced. For example, based on parent interviews, parents reported that they enjoyed the opportunity to learn about their children's lives at school and also came to trust the teachers more. Teachers added that they learned to value families' cultural knowledge and thought about how to use that knowledge more in their everyday teaching. Overall, teachers and parents developed stronger relationships, as well as a sense of being part of a community with similar goals, aims, and concerns for children.

The RISE Project

Consistent with the approaches discussed above, in partnership with a large, urban Head Start program, McWayne, Mistry, Greenfield, Brenneman, and Zan have set about the work of co-constructing with teachers and parents an integrated science, technology, and engineering (STE) curriculum for preschool-age dual language learners through the Readiness through Integrative Science and Engineering (RISE) project. The RISE project underscores the importance of families' contributions to their children's learning, the value of a school curriculum that reflects children's existing knowledge or prior experience, and the importance of a positive and non-hierarchical relationship between parents and teachers.

The RISE project approach is based on the premise that by understanding and appreciating the knowledge and support already available to students at home and in the community, teachers can make connections between these experiences and the classroom curriculum in ways that are truly powerful for students. The Home-School Collaboration (HSC) component of RISE specifically invited immigrant Parent Leaders to join in the process of curriculum co-construction with teachers. One of the strategies to facilitate this type of relationship was to first have discussion meetings with Parent Leaders to create a comfortable space for them to share information and strengthen their leadership skills, as well as to work with teachers separately to help them recognize the power imbalances inherent in the teacher-family relationship and to be able to create a space where reciprocal dialogue with parents could occur. A second strategy involved having parents and teachers engage in joint activities together to build trust (e.g., co-construct cultural features of children's communities using recyclable materials; create a scrapbook of children's activities at home and in the classroom titled "Our Children's Worlds"). Once balanced relationships between teachers and parents were established, teachers came to understand more about children's lived experiences, giving them an increased ability to draw on children's existing knowledge and skills and families' funds of knowledge when designing their STE

classroom curriculum. Emerging evidence suggests this approach has been successful in connecting children's out-of-school experiences within the classroom, as well as connecting teachers and families in reciprocal dialogue.

Conclusion

A one-size-fits-all model of family engagement is not likely to meet the needs of the diverse families served by early childhood education programs across our country. Economic and cultural differences between families and educators often translate into significant discontinuities between home and school contexts. Conflicting values, socialization goals, role demands, and communication expectations and styles can place young children at risk for difficulties as they traverse between the two settings. Despite the fact that many educators agree family-school partnerships are important, as Mapp and Hong report, they often "harbor beliefs, attitudes, and fears about families that hinder their ability to cultivate partnerships" (2010, p. 346). These realities foster disconnection and disengagement between families and schools, and these significant gaps between educators and families need to be better understood to inform our intervention efforts.

Engaging families in the curriculum of the early childhood classroom, in the ways presented here, may be particularly effective for (a) developing parent-teacher relationships built on trust and equal respect, (b) creating curriculum that is culturally responsive and engaging for children, and (c) addressing barriers to family engagement often experienced when mainstream expectations for parental involvement are the only normative reference. It is our view that the field needs to move beyond superficial ways of incorporating families' culture into the classroom (e.g., the "tourism" approach) and develop more meaningful ways to engage families in the formal curriculum of the classroom. There is a specific need for culture-contextualized ways of understanding bridge-building with respect to families. Finding ways to connect families' funds of knowledge and expertise to the classroom, while supporting their own efforts at

home with their children, appear to be promising avenues. Fostering two-way dialogue between parents and teachers, such that teachers may have access to the rich cognitive and cultural resources of families, while also coming to view families as equal partners, also holds great promise for advancing children's learning in the diverse socio-cultural contexts that characterize the landscape of children, families, and schools across our nation today.

FAMILY ENGAGEMENT MODELS

The term *family engagement models* refers to the various approaches to engaging families in early childhood education settings. Family engagement is typically defined as a reciprocal partnership between families and programs focused on supporting children’s healthy development and learning. Research has shown that family engagement contributes not only to children’s developmental growth and early learning but also to improved

parent and family outcomes. Family engagement is considered a key dimension of early childhood education quality. However, research has identified gaps between the desire to engage families and actual practices in early education programs. Various models have been developed to guide and support efforts to understand and implement family engagement. This entry provides a brief history and definition of family engagement models, describes the research and theoretical foundations for the various models, and describes some contemporary applications and future directions for family engagement.

History

Family engagement has a long history in the field of early childhood education. In the 1960s, the federal Head Start program developed one of the field’s most prominent models of family engagement. The Head Start family engagement model required parental involvement both in the classroom and in decision making, and also included a range of family support services. Family child care and community-based early care and education settings have also been touted for their successes in promoting strong parent–provider partnerships through a more informal model based on reciprocal relationships between providers and parents that are built on trust and mutuality.

The importance of family engagement for positive child and family outcomes has been widely documented in the research and practice literature. State and national standards for high-quality early education consistently include family engagement as a core component of quality. The more recent attention to school readiness and preventing the achievement gap has ushered family engagement to the forefront again. It is now widely recognized that family engagement in early education can contribute to the improved school readiness of young children.

Conceptual Models of Family Engagement

The term *family engagement* is frequently used as an umbrella term encompassing a range of approaches or conceptual models for engaging and

partnering with families in the early childhood education context. *Family involvement*, *family partnerships*, *family-centered care*, *parent leadership*, and *family-sensitive care* are all conceptual models for family engagement. Each model has unique and defining characteristics. At the same time, each also shares some characteristics with one or more of the other models.

Key defining dimensions of a family engagement model include (a) how family engagement is defined and (b) the nature of the relationships between families and educators. Some models define the purpose of family engagement in a narrow manner, for example, as applicable specifically and only to the goal of improving children's academic outcomes. Other models define a broader purpose that includes family outcomes such as parental resilience, parenting knowledge, and family well-being. The models also vary in the way that parent-teacher/provider relationships are conceptualized. For example, is the teacher considered the expert in the relationship, or is expertise shared equally, with parents being the expert on their child? Similarly, is power shared between parents and educators, do educators hold the most power, or do parents take the lead? Five models of family engagement are described in this section, highlighting in each how family engagement is defined and how the parent-teacher/provider relationship is conceptualized. Examples of programs that reflect the various models are also identified.

Family involvement is often thought of as the traditional model of engaging parents to support children's learning and academic progress in school. Its focus is on children's academic achievement and how parents can help educators achieve the desired outcomes for children's learning. For example, in a family involvement model, parents are encouraged to attend parent events and meetings, volunteer at the education program, and act as a supportive partner with the child's teacher to foster the child's learning and success in school. Traditionally, this model has reflected an orientation toward the ways parents can help to support children's learning. This is a common approach in K-12 schools and formal early childhood education programs. More recently, this model has been

broadened to reflect a two-way (rather than one-way) relationship, focused on both how the family contributes to supporting the school and how the school can support the family in fostering their children's learning.

This shift to a broader understanding of family involvement may be better reflected now in the *family partnership* model of engagement. This model is broader than just family involvement, and more reciprocal. It focuses on the two-way, reciprocal relationship between families and educational programs. Family partnerships include what school personnel can do and what parents can do, in the home, school, and community contexts. The model also adopts a strength-based approach that recognizes family assets and the need to establish mutually supportive relationships.

Family-centered care is a strength-based, collaborative, consumer-driven model of family engagement. The family unit is the focus here, and children are seen as embedded in the context of their family. In this model, families are seen as holding expertise and the right to make decisions affecting their child. The family context, strengths, culture, and perspective are highly valued. In the family-centered approach, families need not fit into a predetermined or one-size-fits-all program or policy. Instead, services and engagement efforts are flexible and responsive to families' needs and strengths. Family support programs often fit within this model. Family support in education settings engages families through a strength-based approach to foster protective factors that promote healthy child development and family well-being. Family-centered care has been a dominant model in early childhood special education, early intervention, and inclusive educational programs, as well as in other related fields such as social work.

Parent leadership is a model based on family empowerment. Parents and families take the lead on establishing equal partnerships with early education programs to promote child and family well-being. Parents develop skills, knowledge, and networks to be effective leaders and advocates. They take the lead on convening and engaging other parents and educators. In this model, parents rather than professionals play the key role in

setting the goals and agenda for family engagement. Parent leadership during the early childhood years is thought to set the stage for increased parent involvement and leadership as children continue on through their K–12 schooling. One well-known example of the parent leadership model is the Parent Services Project based in California.

Family-sensitive caregiving is the newest model of engagement. This model differs from the others with its dual focus on supporting child outcomes as well as supporting working families. Family-sensitive caregiving emphasizes the important role of early childhood education programs in supporting parental employment and the coordination of work and family. The field of early care and education has a long history as a support for working families, and particularly for working mothers. In order to work, parents need a safe, affordable, high-quality child care arrangement that is available during all the hours parents must work. Family-sensitive caregiving therefore includes a focus on responsiveness and sensitivity to families' work-related needs. For example, early education programs might offer flexible scheduling, informal social supports, and nontraditional operating hours. This model is based on the idea that sensitivity to family needs can reduce stress and strengthen parenting and family well-being. At the same time, it also focuses on engaging with families to support children's healthy development and early learning. This model is the most holistic or inclusive in the scope of its intended impacts.

Contemporary Issues and Applications in Early Childhood Education

Two current issues facing family engagement models are enhancing cultural competence and quality improvement. First, the rapidly growing cultural, linguistic, and family diversity in the United States requires that early childhood education professionals and programs possess a high level of cultural and linguistic competence and proficiency. These competencies are especially important for effective and high-quality family engagement in all of the models presented here. As

a result, growing attention has been paid to strategies for increasing educators' knowledge and skills for cultural competence. Many contemporary efforts to promote family engagement address the importance of cultural and linguistic competencies needed to effectively engage diverse families. For example, Skilled Dialogue is an approach to effectively engaging with families developed by Isaura Barrera. This approach focuses on the importance of honoring diverse perspectives and cultural values. Skilled Dialogue identifies and describes a set of professional dispositions and strategies needed to engage in respectful, reciprocal, and responsive dialogue across differences in ways that result in positive interactions and outcomes.

Quality improvement is another important issue for all the family engagement models. Research indicates a need to improve the quality of family engagement in early education programs. Therefore, it is important to consider various approaches to improving quality. What do individual educators and parents, schools and early childhood programs, and systems need to know and be able to do in order to deliver high-quality family engagement? Research suggests that establishing effective partnerships with families depends upon early educators who have the appropriate attitudes, knowledge, behaviors, and skills. Attitudes associated with effective family engagement include respect and commitment to partnering with families. Knowledge includes knowledge of individual families served, as well as knowledge of family systems, parenting, and cultural competence. Behaviors, skills, and strategies that are effective in engaging families are also essential. These include welcoming families, creating space for families to gather comfortably, greeting each family member by name, and establishing regular two-way communication with families.

In the past, quality improvement typically focused on improving the preparation and training of teachers. However, this individual focus often failed to produce the desired outcomes, largely due to the lack of attention to organizational and systemic barriers to implementing these new practices to improve family engagement. An emerging

evidence base suggests that the organizational culture and its leadership must align with and actively support the implementation of new practices in order to be effective. Teachers work in the context of an organizational system. That system, and all its members, needs to be on the same page in order to effectively engage families. This has led to the emergence of more comprehensive, systems approaches that provide interventions at the individual and organizational levels. This shift from an individual focus to an organizational or system focus represents a major shift for family engagement implementation and improvement.

FAMILY HEALTH

Family health can be defined broadly to include all of the factors that influence a family's functioning. It can include such areas as physical and mental health, financial status, stress, nutrition, access to food and medical care, and many others. The World Health Organization (WHO) defines the determinants of health to include the social and economic environment, the physical environment, and the person's individual characteristics and behaviors. A consideration of family health is important for the study of children because family has been shown to influence the development of children. This entry identifies various parental factors that influence family health and child development.

The environment in which we live shapes our lives. For example, during pregnancy, the mother's body is influenced by effects within her environment. Her level of stress, nutrition, alcohol or drug consumption, and exercise all have the potential to alter the development of her unborn child. In this context the mother is the child's environment. Those things that impact the mother have the possibility to influence the child's development. So where we live matters. The cities, towns, and neighborhoods matter. Access to clean, safe water and fresh air are important and have the potential to impact the health and development of children and adults.

Families are the primary environment for the development of young children. Healthy families have several traits that have been identified by

Dolores Curran and are frequently used in the research literature:

Healthy families have good communication.

Healthy families display mutual affirmation and emotional support to foster individual self-esteem.

Healthy families have a constructive sense of humor and play together.

Healthy families share responsibilities, teach the difference between right and wrong, and have a strong sense of family traditions.

Healthy families foster regular dinner-time conversation and share some leisure time. They seek outside help when problems arise.

When family members evidence these traits and create a healthy environment at home, they are helping children form a strong foundation for their mental health. Parenting behaviors are a critical factor in child development.

Family health refers to the status of a family's well-being. Research shows that a family member's health status is related to a child's development.

The mental health of parents, especially mothers, has been the topic of much research. Maternal depression has been of particular interest. Its symptoms (sadness, negative affect, loss of interest in daily activities, fatigue, and difficulty thinking) are especially troublesome for infants and toddlers. Responsiveness is of particular concern, as mothers with depression are not as responsive to their babies as nondepressed mothers. Over time the lack of consistent interaction can have negative outcomes including delayed cognitive and language development, as well as difficulties with attachment.

Physical health is also a factor in child development. Previous research has shown that parents who have higher levels of education may be better informed about the availability and use of health care and, perhaps also, have better health behavior that confers benefits to their children. Mothers who are in good to excellent health are more likely to have healthy children. Low-income families are more likely to have children with serious health problems.

Parents are seen as the gatekeepers for many things related to their children. One of the most important of these involves choices made regarding nutrition. Food choice and meal planning can be helpful in family health for several reasons. When a parent has knowledge of healthy food selection and food preparation strategies he or she can make wise food choices and control the foods coming into the house, structuring the options available for the child to consume. Further, a parent's awareness of healthy food choices will likely inform the choices that the parent makes regarding food consumption, modeling for his or her child a healthy meal pattern and eating practices.

FAMILY LIFE EDUCATION

Family life education refers to instructional efforts to support healthy functioning of families through preventive approaches whenever possible. The National Council on Family Relations (NCFR), a professional association for multidisciplinary understanding of families, has led the field with the establishment of a national certification for family life educators. Since research has consistently indicated the effectiveness of family engagement in children's

early learning, this entry is written to demonstrate key details about family life education and ways that it links to early childhood education.

Overview

Family life education is viewed as a multidisciplinary profession, thus practitioners come from a variety of backgrounds, including but not limited to family studies, human development, family and consumer science, sociology, social work, psychology, nursing, counseling, and early childhood education. Although each educator is likely to have specialized skills based on his or her professional preparation and experience, the certification process through NCFR requires broad-based content knowledge in order to gain certification as a family life educator. Certified Family Life Educators (CFLEs) must demonstrate knowledge in 10 content areas:

1. Families and individuals in societal contexts: parent–child relationships, work and family concerns, and cultural variations
2. Internal dynamics of families: family stress and crises, special needs in families, parent–child relationships
3. Human growth and development across the life span: developmental change in all family members, processes of child development including physical, cognitive, social, emotional, and moral
4. Human sexuality: reproduction, biological determinants of human development, interpersonal relationships
5. Interpersonal relationships: communication skills, conflict resolution, decision making
6. Family resource management: ways that families allocate resources, consumer issues, environmental factors
7. Parent education and guidance: parenting rights and responsibilities, variations in parenting, parenting practices
8. Family law and public policy: social services, education, civil rights
9. Professional ethics and practice: social attitudes and values, respecting diversity, consequences of value choices
10. Family life education methodology: planning and implementing, evaluating, sensitivity to diversity

Although it is possible for professionals to refer to themselves as family life educators without having earned the NCFR certification, those who hold a national certificate have proven themselves through a meticulous screening process to have depth and breadth in their understanding of family functioning and issues. In addition to content, CFLEs are expected to possess strong communication skills, good decision-making skills, positive self-esteem, and an ability to form healthy interpersonal relationships. Further, CFLEs understand that issues within the context of the family are best addressed from a systems perspective—seeing families as one part of the larger society.

Formats for family life education vary and include sessions for groups of learners in a classroom-type setting, educational materials such as flyers or booklets, and technology-based instruction. As indicated by NCFR, family life education is applied in three categories: practice, administration, and promotion or advocacy. Family life educators who engage as practitioners are likely to teach or create programs and curricula; those who administer will typically manage, organize, or coordinate programs; and those who promote are advocates for public policy changes and awareness campaigns. It is possible for a family life educator to occupy more than one of these roles at a given time. For example, a director may coordinate a parenting support agency, lead an educational program for foster parents, and advocate for public policy that increases support for foster families.

Links to Early Childhood Education

Early childhood teacher certification preparation programs typically would address only a few of the family life education content areas. Generally, significant attention is given to child development, at least through age 8 years, with some programs

requiring a life-span development perspective. Variations in the breadth and depth of consideration provided to family engagement in early childhood education and educator preparation have been well established. Some early childhood teacher candidates are prepared to understand families in the context of society as well as internal dynamics of families. Strong preparation programs highlight cultural variations and implications for working with diverse families and working with the special needs that exist within families, such as effectively teaching a child who has been identified with a serious disability or medical condition. On the other hand, some early education teacher preparation programs gloss over these family life education content areas and emphasize practices such as parent-teacher conference strategies.

The topic of ethics for early childhood professionals has a different focus than is appropriate for family life educators. Emphasis in early childhood education is on teaching children, whereas family life educators are most often teaching adults. However, commonalities for the two professions exist in relation to respecting diversity, sensitivity to individuals, and applying current knowledge regarding best practices.

Although teachers of young children are expected to have skills for effective interpersonal communication, few certification programs provide explicit instruction in effective communication. Many expect that teachers will gain communication skills through practical experience such as student teaching or internships. Understanding parenting is another content area that is often not explicitly addressed in early education teacher certification programs, leaving the topic wide open for teacher biases from limited personal experience.

The remaining content areas, not surprisingly, are rarely included in early childhood teacher preparation: human sexuality, family resource management, family law and public policy, and family life education methodology. These family life education content areas focus more on adult family members or family units, and early education teacher preparation will have greater attention to

planning, teaching, and assessing young children's learning and development.

Strategies for Infusing Family Life Education Into Early Childhood Education

Most preparation programs, early childhood centers, and schools give little attention to family life education in initial licensing or continuing professional development of early childhood educators. For this reason, recommended strategies herein involve various ways to work with one or more family life educators and to support early childhood teachers in applying family life education strategies.

- Hire a family life education consultant to provide support for early childhood teachers as they work to effectively engage families in their children's education.
- Provide professional development support for early childhood teachers to complete coursework or other available training related to family life education.
- Hire a family life education consultant to collaborate with early childhood teachers as they jointly lead valuable programs for parents and/or other family members.
- Encourage early childhood educators to search for family life education topics online, particularly fact sheets created by Cooperative Extension child development and family experts.
- Encourage family life educators to have depth in the area of family engagement in children's education by reviewing evidence from family involvement literature regarding successful practices, from family partnership research such as that available on the Harvard Family Research Project website, and valuable programs such as nurse-family home visiting.

FAMILY LITERACY MOVEMENT

Family literacy refers to parent/family interactions with children occurring at home or in the community that support the child's early literacy learning. Contemporary educational research provides evidence that all parents and families are capable of contributing to the early literacy growth and development of children. The manner in which parents define their roles might differ according to prior formal education experiences, cultural models, discourse practices, and aspirations for their child. This entry discusses the growing prominence of family literacy research across multiple disciplines, the theoretical shift that has occurred within the field of family literacy research, and

how this shift has created a space to consider families' cultural literacy practices. Particular attention is afforded to the discussion of current research findings related to family literacy.

Overview

Children live their lives in two worlds—the first world consisting of home and community, and the second consisting of the school. When these worlds fail to recognize and appreciate each other, children experience challenges as they negotiate these differing worlds and the literacy practices that they teach and promote. The field of family literacy examines the variables arising from these two worlds that influence a child's early literacy acquisition and development.

Many contemporary family literacy scholars have attested that family literacy is not defined by a single, narrow definition since that would not fully address the complexity of families and the multiple literacies that are part of their daily lives. Scholars from the disciplines of literacy, early childhood education, educational psychology, sociology, and anthropology strive to further the collective understanding of the complexities of family literacy. As such, family literacy has currently come to be widely interpreted, ultimately being defined in a manner best fitting the discipline and context in which it is being applied. In addition, major research findings pertain to a variety of populations, including (a) families with children who have disabilities, (b) families who represent culturally marginalized groups, (c) families who primarily speak a language other than English, and (d) mainstream groups.

Research

The study of family literacy was a very polarizing field of study at its inception in 1983 when Denny Taylor published her dissertation, *Family Literacy: Young Children Learning to Read and Write*. Early family literacy research tended to portray differing family literacy practices as deficits to children's early literacy learning. Recently, a shift has occurred within the field so that these

differing family literacy practices are now more readily viewed as enriching rather than detracting from early literacy learning. Despite the controversy within the field regarding the nature and value of differing family literacy practices, family literacy has been an ever-present influence on the early literacy development of children.

Contemporary family literacy research has predominately focused on specific literacy interventions, the home literacy environment, or parent-child interactions during shared book reading or shared writing. Some of the major research findings relevant to these foci of family literacy research include the following:

- Family literacy intervention programs differ in purpose since they tend to be designed according to one of the two following models: (1) the *deficit model*, which focuses on changing family literacy practices so that they align with formal school literacy practices, or (2) the *enrichment model*, which uses family literacy practices as a foundation for building new literacy knowledge.
- Home literacy environments supportive of early literacy development incorporate (a) multiple opportunities to share readings between adults and children; (b) access to literacy resources and materials; and (c) quality interactions that support development of oral language, print knowledge, and word recognition skills.
- Factors influencing the frequency of parent-child interactions during shared book reading, shared writing, or other literacy activities include socioeconomic status, level of parents' education, and if parents were English language learners.

Even though many family literacy scholars have shifted their view of differing family literacy practices, there are still limitations in family literacy research. One prominent limitation is the continued tendency for research studies and intervention models to prefer literacy practices and interventions aligned with school literacy practices. This has resulted in a limited number of studies that thoroughly examine families' culture and literacy practices and how these practices, even though

different from school literacy practices, contribute to a child's literacy acquisition and development within school contexts. Guofang Li and Luis Moll are two scholars who have suggested research approaches that support study of families' culture and literacy practices and the contributions they afford to early literacy development.

FAMILY PARTNERSHIPS

Family partnerships are one approach to develop family involvement in a child's education. Family partnerships focus on creating close working relationships between a teacher or other program staff member and a child's parents (or other primary caregivers, such as grandparents.). The partnership approach to family involvement is valued because such relationships among family members and teachers rely on adults working toward common goals for children, require communication and collaboration, and imply that while partners may bring different contributions, all partners are accountable for maintaining the relationship. In early childhood settings, partners work together primarily to support the optimal development of children.

The broader concept of family involvement and the more recently discussed concept of family engagement have long been identified as an important influence on children's success in school, with a plethora of research finding strong correlations with parent involvement and the children's academic performance. This finding holds even when factoring out such confounding variables as income, maternal education, and other demographic indicators. Traditional concepts of family involvement, however, focused primarily on the family in the service of the school; examples include parents volunteering at school, parents as audience members at school events, parent attendance at parent-teacher organization events, and families assisting with fundraising.

More refined research findings have been interpreted to suggest that perhaps it is not so much a family in service to the school that supports their child's success, but a family's involvement with their child's education. For example, children are more successful in school when the family holds high, yet developmentally appropriate, expectations for the child's performance and when the family provides experiences in support of learning such as community outings and reading to the child at home.

Theoretical Foundations for Family Partnerships

Family partnerships are supported by Urie Bronfenbrenner's bioecological model of development. This theoretical approach suggests that the child rests at the center of five systems—the micro-, meso-, exo-, macro-, and chronosystem—and that each of these systems directly and/or indirectly impacts the child's development. The microsystem in this model refers to the different structures or institutions that have direct interaction with the child, essentially societal structures that daily “touch” the child; these include the child's family, the child's school, the neighborhood where the child lives, the peers the child plays with, and possibly the family's church. The mesosystem refers to how these direct influences on development interact with each other to influence the individual's development; the mesosystem is composed of the relationships among the structures of the microsystem. Exosystem includes the larger institutions and structures that influence but do not directly interact with the individual (for example, adult family members' work environments and local school board policies). The societal beliefs and values that provide a sociocultural context for all of these structures is the macrosystem; society's values and culture indirectly impact a child's development. Chronosystem denotes the events that occur over the lifetime.

Family partnerships epitomize the mesosystem as they describe the relationship between the family and school, two important microsystem structures. Bioecological theory posits that the better the relationships within the mesosystem, the more positive the impact on the individual's development. If this theoretical approach holds true, strong family partnerships are an important method to support children's positive developmental outcomes.

Family systems theory also plays a part in providing a theoretical foundation for family partnerships. Systems theory, built on the assumption that the whole is greater than the sum of its parts, posits that what impacts one part of a family (system) impacts all parts of the family (system). Therefore,

if there are family stressors (e.g., unemployment, illness, emotional stress) that impact the family as a whole, these issues also directly or indirectly impact the child. Improving the family's overall status should then improve developmental outcomes for the child. Family partnerships often provide a context in which the concerns of the family as a whole may be addressed as well as concerns specific to the child being served by the program.

Early Childhood Education and Family Partnerships

Partnering with families is a central pillar of developmentally appropriate practices in early childhood education. Due to the vulnerable nature of a young child, communication among all those who care for the child is important to facilitate the child's daily care and optimal development. Family members and program staff provide differing perspectives of the child. While teachers and other early education professionals bring an expertise and knowledge base to their observation of any child, family members bring expertise on the individual child.

National Association for the Education of Young Children's Developmentally Appropriate Practice Position Statement

In 2009, the National Association for the Education of Young Children (NAEYC) published a third edition of its position statement on developmentally appropriate practice. Several aspects of the position statement address the importance of family. For example, understanding the child and family's social and cultural contexts is a core consideration. As described earlier in the bioecological macrosystem, the cultural context has a strong influence on the child's development. Family partnerships allow families and programs to share information so that both partners can better understand the influence of culture on the child.

This partnership may be even more important for instances when there is limited cultural commonality among the family and program staff

members. Opportunities to interact in a true partnership give all partners the potential to better understand different cultural values and practices. Better understanding of a child's cultural context on the part of the program staff should lead to improved outcomes for the child.

Another guideline for developmentally appropriate practice that indicates the importance of family partnerships is found in Guideline 2, Teaching to Enhance Development and Learning, and Guideline 4, Assessing Children's Development and Learning. Teachers are responsible for getting to know the children in their care and the people most significant in the child's life. The teacher has the responsibility to help the family understand the child's developmental levels, strengths, and challenges. Best practice for the assessment of the child in the early childhood setting also requires a strong teacher-family relationship. Families should be involved in the process of assessing their child and in making decisions about the child based on that assessment data. These interactions also provide a strong indication of the need for strong relationships with families.

No doubt, the strongest support from NAEYC's position paper for family partnerships is in Guideline 5, Establishing Reciprocal Relationships With Families. The position paper clearly states that the complex relationship between teachers and parents is essentially a learning community. While using the term "reciprocal relationships," NAEYC defines a partnership in the supporting text. This guideline includes such expectations as working together toward shared goals, working collaboratively with families using two-way communication, providing multiple opportunities for families to participate in decision making for their own child and for engagement with the program, respecting family choices and goals for their children within the program's context, and engaging together in planning for the child.

Early Care and Education Programs With a Family Partnership Focus

Family partnerships are a type of family involvement closely related to early childhood education.

Head Start/Early Head Start, early intervention services provided under the Individuals with Disabilities Education Act (IDEA) Part C, and home visiting programs are three programs in which family partnership is central to the programs' implementation. In each of these cases, there is a strong emphasis on a member of the program staff creating a close working relationship with the child's family. Family partnerships, by definition, apply a systems approach within these programs, with one focus on working with the family to identify goals not only for the child, but also for the family or parent. Staff members and family members meet, define areas of concern, create goals for the child and family, and work toward meeting those goals.

IDEA Part C family services include writing an individual family service plan (IFSP) for the family. IDEA law clearly indicates that early intervention professionals and families should partner in the development of the IFSP. Much as described earlier, the IFSP should reflect the family's goals for the child and the family; it should be written in partnership with the family and not completed by program staff, for the family.

Since 2010, home visiting programs have surged in number due to funding through the Maternal, Infant, and Early Childhood Home Visiting (MIECHV) Program of the Affordable Care Act. The parent is the primary recipient of services in home visiting programs. The Nurse-Family Partnership model is an example of a home visiting program with a strong research evidence of its effectiveness on children and families. Other home visiting models that embrace a partnership approach include Parents as Teachers (PAT) and Home Instruction for Parents and Preschool Youngsters (HIPPI).

Developing Effective Family Partnerships

Building effective family partnerships requires knowledge, skills, dispositions, and resources, especially the resource of time. A key component of a working partnership is communication. The teacher is required to communicate with the family

and must provide avenues for the family to communicate with the teacher. Communication works best when it is positive, consistent, purposeful, and timely. Partnerships take time to develop, so teachers should begin communication early in the relationship and continue the two-way communication. Multiple modes of communication will generally be more effective and allow contact by telephone, e-mail, written communication, and of course face-to-face dialogue. Some families may be more comfortable with one format while other families may rely on a different medium.

Flexibility is necessary in more than communication modes. Partnerships are flexible, building on the strengths, interests, and needs of the partners. Work schedules, transportation issues, and parents' discomfort with school due to their own unhappy experiences are some considerations for providing flexibility when developing partnerships with families. Meeting families in their own home during home visits, or at neutral sites such as community centers rather than the school, may be a good option to offer families.

The teacher's disposition will play a role in creating strong partnerships. If both parties do not believe there is value in the partnership, it is likely to fail. That may mean staff must both exhibit confidence in the importance of the partnership and provide families with clear gains for their own participation. Cultural competence is also necessary for strong partnerships to develop. Cultural competence can be considered as attitudes, knowledge, and skills to work effectively with persons from cultures or belief systems other than one's own. As stated earlier, the social and cultural context of a child and family has a strong influence on the child's development. Teachers need cultural competence in order to be most effective at navigating the impact of culture on the child's development and to facilitate the partnership with family members.

Ultimately, family partnerships are dependent on the individuals involved. Best practices in early childhood education, as defined by NAEYC's developmentally appropriate practice, reinforce the importance of developing partnerships with families in order to provide the best environments for young

children. Creating relationships with families means having the skills to operate in cross-cultural situations, being able to communicate in multiple media, and taking the time to put these into effect with the families of each child served. It is a fundamental part of several early childhood programs.

FAMILY STRENGTHS

Children's development and character are primarily due to the influence of the family in which they belong. The family in turn impacts and affects the ways in which a community and society function. Families are the foundation for all cultures around the world. Although families are very diverse, as a unit, they accomplish similar tasks including bearing and rearing children, providing the basic needs of the members in the family, establishing family traditions, and teaching responsibility. Families play a major role in how well children do in school and perform as adults and how they will contribute to society.

Early childhood education (ECE) professionals are challenged to continue the foundational work begun within the family unit in developing a child's whole being: physical, cognitive, social, emotional, aesthetic, and language. ECE professionals also need to acknowledge the strengths of the parent and work with the parent to enable them, as the professionals, to better understand the child. This relationship is a two-way endeavor that aims to help children move in a positive direction, in all aspects of their being, to be successful in school and in the outside environment. Crucial to this endeavor is mindfulness that all families have strengths and a commitment to look for the strengths within each family. Families can be two-parent families with no children; two-parent families with children; single-parent families, male or female headed; families headed by grandparents; a couple with no children; gay or lesbian families; and families headed by a relative of the parents, who have died or are incarcerated. Family types do not take away from the family strengths in each unit.

This entry reviews best practices for early childhood professionals to identify and build on the characteristics of families through the lens of a strength-based model. This model has been around for over 40 years. Included in this discussion will be a definition of strength-based perspective, qualities of strong families, and ways to build and maintain these qualities in children as they enter yet another community—the early childhood classroom.

Family Strength Perspective

When working with children, it is easy to find “the good, the bad, and the ugly.” Opportunities to meet the parents of the children certainly enhance our understanding of the makeup of the child. However, caution must be taken to avoid the human tendency to identify and focus on deficits and instead to center attention on strengths. Most often, when we look for problems we can only see problems; however, it is a fact that if we look for the strengths in children and families, we will clearly see the strengths. Furthermore, focusing on negative characteristics overshadows our vision to see the positive characteristics found within children and families. Early childhood professionals need to consider this paradigm shift from a deficit-based model to a more strength-based model as the most effective way to support children and families. The focus will be on the internal family functions that should be the same, no matter the family “type.”

Defining a Strength-Based Perspective

A strength-based perspective is simply an optimistic and positive view toward life. This perspective can be applied to many facets of life and is gaining momentum in the areas of behavioral health, human development, counseling, and psychology, and in the area of early childhood education. For those who educate young children, the strength-based perspective addresses the methods, strategies, and policies that draw upon the strengths of children, families, and communities.

Several principles of a strength-based perspective have been identified and deserve serious consideration from early childhood professionals, whose goal is to support the development of families. Some of these key principles include the following beliefs:

- All families have strengths, but families also encounter challenges and have areas of growth.
- Looking for strengths will uncover the strengths of a family, but focusing on families’ weaknesses will identify the weaknesses of the family unit.
- There are various types of family structures, but the strength of a family does not lie in the structure of a family but in the *function* of the family.
- Strengths develop over time, and a professional provides resources that will assist families in becoming strong units.

Professionals who view children and families from the lens of a strength-based perspective recognize that each individual member within the family has traits that contribute to the strong family unit. A trait can be explained as a distinguishing quality or characteristic, and the challenge to the early childhood professional is to identify and foster the development of these qualities within each child in their classroom.

Qualities of Strong Families

Researchers have studied and identified common traits found in strong, healthy families. These traits have been found in families of different types, social backgrounds, nationalities, and race. Below is a list of the traits and brief descriptions.

Appreciation. Appreciation means caring for each other and respecting each individual within the family unit. The appreciation also results in valuing the time spent with one another. The more time family members spend together or separately with parents, the more positive it is for that child in the future. It is about both the quantity of time and the quality of time spent together. Families notice the skills, qualities, and achievements of each individual that contributes to the well-being of the family. When families appreciate each member, a deep sense of caring for each family member occurs. Some researchers would include the word *love* as part of the appreciation trait.

Positive Communication. Effective communication patterns are essential. Communication is frequent, open, and honest. Members are willing to listen and openly share their feelings without fear of ridicule or rejection. Family members give compliments to one another and learn to provide

constructive feedback. Parents and other family members must also be aware of the nonverbal communications that are taking place in a family. Parents need to listen to their child and their preferences rather than planning around what the parent wants to do or thinks the child wants to do. The focus needs to be on the child's expectation first. Children often want to just be heard and enjoy the company of a parent or grandparent and may not be really interested in suggestions or solving a problem.

Adaptability. Adaptability is defined as the ability to cope with change and stress. Although all families develop rules and routines, these habits are constantly reshaped by births, divorce, marriage, sickness, and death within the family. Families that are adaptable recognize the changes that occur and strive to maintain a degree of flexibility and openness to the changes. Serving as one strong foundational unit, members draw upon the unique talents of one another to survive and develop strength through these experiences.

Commitment. Strong families show a commitment to one another due to the recognition and acceptance of the worth of each individual. Families learn to value the things that make them unique such as the traditions they hold onto. A tradition can be defined as an activity or an event that holds special meaning, such as how to celebrate birthdays and holidays, church attendance, or family vacations. Through these commitments, a family strengthens the bond of togetherness.

Clear Roles. When families clearly define the roles of each member the family realizes how easy it becomes to work together to accomplish goals. The roles must be realistic and developmentally appropriate for each person. The roles will change over time as children mature. Individuals in any organization and especially in families are more apt to carry out their individual roles and responsibilities if given the opportunity for input. Although parents serve as leaders, when they invite and encourage the thoughts and ideas of their children when making decisions the responsibilities

are more apt to be carried through. Young children often model the practices set forth by parents and siblings when making decisions, a skill that develops over time and is needed to become successful adults.

Spirituality. A spiritual family is one that believes in something or someone greater. In some families, their shared spiritual beliefs are often recognized in both the challenging times and rewarding times, such as the loss of loved ones or job promotions. The spiritual belief usually connects families to other people or groups that share in their beliefs and philosophies within the community.

Community and Family Ties. At some point, families recognize that they do not live in a vacuum and come to rely on additional love and support freely given by extended family members such as aunts, grandparents, uncles, and cousins. Strong families naturally find rich resources of support within their communities when they become involved with their child's schools, church, and other organizations that support their beliefs and ideals of family. As parents become involved citizens by serving the community as members of city councils or school boards, or volunteer in community projects, they demonstrate to children the strong connection family has to a greater entity.

Encouragement of Individuals. Individuals all have experiences that call for encouragement to continue. The level and type of encouragement come from the family unit as well as the community. Members tend to seek out the support from those who have experienced a similar situation and rely on their advice to move forward. Families celebrate each other's successes.

Commitment to Family. Each member of a strong family unit is committed to one another. A loyalty to each other develops over time and through every experience families' share. Individuals recognize the strengths and worth of one another and call upon the strength and bond they share as a family unit.

Although these nine common traits are found within strong family units, these traits can

continually be developed and strengthened outside the home. Early childhood teachers can provide experiences through strategies implemented within their classroom that work to foster and strengthen the development of each child. As children broaden their world and grow from the family unit to a classroom community, these traits must continually be fostered as skills that in turn will positively affect the communities to which they belong.

Building and Maintaining Qualities in an Early Childhood Classroom

As a child moves from the family unit into a classroom community, it is crucial for the early childhood teacher to identify these qualities within each child. As noted before, not all children may have come from a strong family. Educators must observe children through the lens of the strength-based perspective rather than the deficit perspective. When looking for the strengths, teachers will discover that each child has developed some strengths to a certain degree. The challenge as a teacher is to foster these qualities found with strong families, within their own classroom where children are transitioning from the family unit to a classroom community.

Early childhood teachers must provide experiences within their classroom community that will continue to foster those qualities that are noted to build healthy and strong communities. Below are a few suggested strategies that can be used to strengthen family systems and be transferred to the classroom community as well.

- Spend quality time connecting with each child at least once a week. Quality time could be referred to as one-on-one time spent in exploring the wants, needs, and interests of the child.
- Respond to the children with patience and respect in regard to their feelings and their abilities.
- Provide time within the week where children are asked to share their accomplishments. In the home this can be done around mealtime; at school it can be done during morning meetings.
- Hold classroom meetings where all community members (children) have an opportunity to talk openly without fear of ridicule or rejection.
- Encourage open communication, accomplished not only through words but also through actions and drawings. Listen with an open heart and compassion.

Conclusion

Aristotle believed that “the whole is greater than the sum of its parts.” As early childhood educators, we acknowledge that a family is only as strong as the individuals within the unit. We begin to identify the characteristics of strong families when we examine the qualities of those individuals within the unit. Most important, our view of families and individuals must be examined through the lens of a strength-based perspective whereby we focus on the optimistic and positive occurrences within each family structure. Educators come to realize that the best way to serve families is to collaborate with them, acknowledging the knowledge and experiences they have encountered, while respecting the wisdom and resources they have developed as a family unit.

FAMILY STRUCTURE

Family structure refers to the configuration of family members in a household. In light of demographic changes in the United States over the past 50 years, the term family structure is typically used by social scientists to refer to one of the following arrangements: married-parent households, single-parent households, and cohabiting-parent households. Family structure is linked to child well-being and has implications for parents' use of early care and education settings. This entry examines recent demographic changes in family structure in the United States, how family structure affects children, and implications for the use of early care and education.

Demographic Changes

Over the past 50 years, the marriage rate in the United States has seen a dramatic decline. In 1960, 72% of adults were married. By 2008, this percentage had dropped to 52%. As the marriage rate declined, the rate of unmarried births increased sharply. The share of births to unmarried women rose from 5% in 1960 to 41% in 2008. These changes are closely tied to both socioeconomic status and race/ethnicity. For instance, college

graduates are now much more likely to be married than those with a high school diploma or less. In terms of race/ethnicity, although marriage rates have fallen among Whites, Hispanics, and Blacks, the drop has been most pronounced among Blacks. In 2008, 56% of Whites, 50% of Hispanics, and 32% of Blacks were married. Consistent with this trend, Black women have the highest unmarried birth rate. As of 2012, 72% of births to Black mothers were to unmarried women. Rates were 54% and 29% for Hispanic and White mothers, respectively.

As a result of these demographic changes, American children are growing up in households with a more varied array of family structure configurations than ever before. In 2008, approximately 70% of children under age 18 who lived with a parent lived with married parents, 15% had parents who were separated or divorced, and 14% had parents who were never married. This percentage of children in never-married-parent households, however, masks substantial variation. Specifically, it fails to capture the distinction between single parents and cohabiting parents, who are unmarried parents who live together. Cohabitation has been on the rise since the 1970s. In 2010, 23% of recent births were to cohabiting parents, a noteworthy increase from 14% in 2002. Furthermore, approximately 40% of children are estimated to live in a cohabiting household at some point in their childhood. Cohabitation can take many forms. It can consist of two biological parents living together or a biological parent and the parent's partner. It can be a precursor to marriage, a temporary alternative to marriage, or an alternative to single parenthood. Regardless of the form they take, cohabiting relationships tend to be short-lived.

Family Structure and Child Development

There is substantial evidence that children born to both single and cohabiting parents are at greater risk for poor developmental outcomes, including lower scores on standardized tests of cognitive ability and higher levels of behavior problems, than children born to married parents. This pattern

is partly due to the fact that single and cohabiting parents are more likely to be socioeconomically disadvantaged than married parents. They typically have lower incomes, fewer years of education, and higher rates of maternal depression, all of which are associated with poorer developmental outcomes for children. There is some evidence to suggest that children of single mothers may fare better than those who live with cohabiting partners (one parent and the parent's romantic partner), but other studies have found no differences in the well-being of children of single and cohabiting parents. A separate strand of research suggests that marital quality may moderate these associations. For instance, children may actually benefit from marital disruption (separation or divorce) if their parents have a high-conflict relationship.

Implications for Early Care and Education

The growth in the number of children born to unmarried parents has implications for patterns of use of nonparental early care and education (ECE) arrangements. ECE arrangements are particularly crucial for unmarried working mothers, who are more likely to have to balance work and family on their own. Approximately half of all unmarried mothers rely on ECE of some kind. Most of these mothers use relative care, which is care provided by the child's relative in either the child's home or the relative's home. Additionally, a substantial share use formal center-based care, which includes Early Head Start, Head Start, and publicly funded preschool programs. Not surprisingly, single mothers are more likely to rely on ECE than cohabiting mothers. This is likely because cohabiting mothers can more easily rely on their child's father to provide child care or support, allowing them to balance work and family without the use of ECE arrangements. Relative care is typically less expensive than other ECE arrangements and may be more convenient for mothers who work unusual hours. However, relative care is unregulated (as opposed to center-based care arrangements, which have to meet public health and

safety regulations). Therefore, a large share of children in unmarried-parent households, most of whom are socioeconomically disadvantaged, spend their days in unregulated ECE settings. This raises concerns about the health and well-being of this group of children and suggests that policy makers should focus on making low-cost, *regulated* ECE arrangements available to this particularly vulnerable group of parents and children.

FAMILY STRUCTURE DIVERSITY IN THE EARLY CHILDHOOD PROGRAM

All family structures serve similar purposes, paramount among which is to take care of, socialize, educate, and protect children until they reach young adulthood. Inherent in the professional ethics of early childhood education is the expectation that each child's family will be treated with respect and that children will be helped to feel proud and strong about their specific family. Although some

still define the term *family* to mean a husband and wife and their biological children living together under one roof, the reality is that many types of family structures exist.

All young children think the family in which they live is simply how families are. It is when children enter group programs outside of their homes that they often discover that there are many kinds of families and that the important adults in those programs may or may not think of their family as normal or acceptable. The degree to which the early childhood education (ECE) program makes a family visible and warmly included makes a huge difference in the ease or difficulty of a child developing a positive sense of self and of belonging.

Terms for family structures vary from region to region and from family to family. It is important to find out which term(s) each family uses to name itself, and for teachers to use those terms with children. It is essential to recognize that the structure of a family does not indicate the degree to which the family does or does not work effectively, is or is not loving and kind, and does or does not have problems with addictions, anger, money, and so on. At the same time, staff need to be aware that different family structures may have quite different issues, needs, strengths, and values that require different approaches and supports from ECE staff. The following descriptions of family structures are not exclusive; several of the terms may describe a family at a given time.

Adoptive Family. A family where one or more of the children has been adopted. Any structure of family may also be an adoptive family. A *transracial adoptive family* is one where the adopted child is of a different racial identity group than the parents. Sometimes children (as well as adults) use the term “real parents” to mean “birth parents.” ECE staff should be clear that the adoptive parents are the actual parents because they are the ones raising the child. It is essential for staff not to automatically assume that any problems a child may be having are due to adoption.

Biracial or Multiracial Family. A family where the parents are members of different racial identity

groups. Children in these families are not half-and-half, nor do they have to choose one identity over another. Each child is fully who they are. As racial identity remains one of the most contentious and difficult issues in the United States, ECE staff must be prepared to listen carefully and respectfully to what each family wants their child to value about her or his identities. This also applies to transracial adoptive families.

Blended Family. A family in which one or both of the members has a child or children from a prior relationship. Families may use a variety of terms for the various family members or simply call them by name. Relatives from the original family, or half-siblings, step-grandparents, and so on may or may not play a major role in the children’s lives. ECE staff should follow the family’s lead in identifying who the people are that the child thinks of as family and include those people in any family curriculum or activities.

“Broken Home.” A highly derogatory term inappropriately and inaccurately used to describe the homes of children from divorced families.

Co-Custody Family (Joint Custody Family). A family in which parents who do not live together share legal responsibility for their children. Children may alternate living with each parent or live with one and have visitation with the other. ECE staff should find out which parent is responsible for the child on which days and who will be picking up the child. Children should be supported to acknowledge both families and never be put into the position of having to choose which is most important.

Conditionally Separated Families. A family in which a member is separated from the rest of the family. This may be due to circumstances such as employment far away, military service, incarceration, or hospitalization. They remain significant members of the family. ECE staff can help children in these families to deal with what is often a stressful time. Children can stay connected by making drawings, dictating letters or stories about favorite activities at school, and having a special calendar

that marks off the days until the family will be reunited. ECE staff should avoid assurances about the unknown such as telling children that a member of the military will be fine or that someone who is incarcerated will be home soon.

Extended Family. A family where grandparents, aunts, uncles, and cousins play significant roles in the children's upbringing. This can include relatives living with the children or those who don't. Extended family may be in *addition* to the child's parents or *instead* of the child's parents. In school invitations, conferences, and letters, ECE staff should include all the people in an extended family who are important in the day-to-day life of the child. Staff need to be aware that grandparents may have as much or more voice in decisions as parents, and cousins may be as close as siblings.

Foster Family. A family where one or more of the children is legally a temporary member of the household. This "temporary period" can be as short as a few days or as long as the child's entire childhood. *Kinship care families* are foster families where there is a legal arrangement for the child to be cared for by relatives of one of the parents. ECE staff should use the terms used by foster children to refer to their foster parents and ask the foster parents what they have told the child about the likelihood of reuniting with the absent family. If it is permissible for the original parents to visit, staff should make them welcome. A foster child should never be asked to choose who is most important to him or her.

Immigrant Family. A family where the parents have immigrated to the United States as adults. Their children may or may not be immigrants. They and their children may or may not be U.S. citizens. Some family members may continue to live in the country of origin, but still be significant figures in the life of the child. (See section on *transnational families*.) All immigrant families bring with them a set of culturally based behaviors for raising their children, and each of these families is

continually navigating between what made sense in their country of origin and what is needed in their new country. ECE programs must take special care to strengthen the bonds between the child and the family. It is the staff's responsibility to find ways of incorporating home cultures in respectful and welcoming ways and to reconcile cultural beliefs that may be in conflict with specific traditional ECE. Supporting the child's home language (the child's mother tongue) is as essential for the child's thriving as is supporting the child as an English language learner.

Lesbian, Gay, Bisexual, or Transgender Family. A family where one or both of the parents is bisexual, gay, lesbian, or transgender. This may be a two-parent family, an adoptive family, a single-parent family, or an extended family. Some families are beginning to use the term *queer families*; however, this term is still pejorative in parts of the country and to some families. LGBT families often face significant social prejudice, and in parts of the United States family members may not have full legal rights to their children. It is up to the early childhood professionals to demonstrate that the children's program is a safe place for families to be open about who they are and no one but the members of the family has the right to "out" a family (reveal their sexual orientation) to anyone else. Staff should find out what terms the child uses to describe her or his parents and be sure that all letters, forms, invitations, and so on use language that makes clear that these families are welcome.

Migrant Family. A family that moves regularly to places where they have employment. Farmworker families who move with the crop seasons are the most common example. Military families may also lead a migrant life, with frequent relocation, often on short notice. Children may have a relatively stable community of people who move together—or the family may know no one in each new setting. It will often take longer for the migrant child to settle into a new program and make important ties to teachers and other children. ECE staff can support these children by helping them recall and

talk about places they have been. When families leave for a new location, they should be given documentation of their child's experiences, and the children given pictures to remember friends, teachers, and activities.

Nuclear Family. A family consisting of a married man and woman with their biological children. This family form is the one most reinforced in dominant society. ECE staff can help children understand that the two-parent, heterosexual family is one kind of family among many others. It is essential that early childhood teachers not assume that just because a family has a nuclear structure, they do not need thoughtful support and community connection.

Single-Parent Family. A family with a father or mother who is solely responsible for raising a child who either was born to the parent or was adopted. The parent may have chosen to be a single parent or may have become one by life circumstances. The other parent may have been part of the family at one time or not at all. ECE staff should find out what other supports the single parent has and which other people play a significant role in the child's life. It may be particularly significant for this type of family that the early childhood program builds a caring community of parents.

Transnational Family. A family that lives in more than one country. They may spend part of each year in their country of origin, returning to the United States on a regular basis. The child may spend time being cared for by different family members in each country. Culture clash may be a primary issue for these families as they work to have their children be at home in both countries. ECE staff should pay particular attention to the areas where parents are uncomfortable with ECE approaches and problem solve with the families to lessen the disequilibrium. Staff should learn about the words the child uses for his or her various family members in both countries and what (if any) kinds of group care the child has experienced.

Working-Class or Poverty-Class Family. For low-income families, economic circumstances impact every decision of their daily lives. Children in these families rarely find their experiences reflected in children's books or media, or if visible at all, only reflected in negative ways. They may wear second-hand clothes, go without new toys or hot-trend products, be cared for in crowded clinics, and experience homelessness. ECE staff must be very careful not to equate the economic-based struggles these families face with "bad" parenting. Coming late to school is often the result of having to use unreliable public transportation or unrepaired cars. Concern over keeping clothes clean at school may be connected to the difficulties and costs of using laundromats. Getting child care to attend meetings, or getting permission to miss work, may make it difficult for parents to participate. The use of food for art projects is a painful and insulting experience for families where access to food is a source of worry. Staff should avoid the insulting phrase "lower class" and use books that celebrate the important contributions of all types of work that family members do.

Families Coping With Disabilities. Family members with disabilities may be present in families with any of the structures just described. These disabilities may or may not be visible. Whatever other issues they may have, there is always the addition of having to continually adjust and shift to meet the needs of the person with the disability. For most of these families, the search for resources is a major and ongoing struggle. ECE programs are required by federal law to adapt classrooms and instruction for the inclusion of children with disabilities. It is also important for programs to adapt so that family members can be involved. ECE staff should openly discuss the disability with the family, find out what words the child has for describing the specifics, and use the family's terminology in the classroom. While these families often have special needs, they are not helped by pity or by pretending they do not need accommodation. The family itself is the expert on what will be most helpful.

Effective early childhood practice requires that teachers and administrators understand the fundamental, long-term, powerful relationship between children and their families. As children develop their deepest social identities, they are paying attention to adult attitudes and societal cues even before they have any language to describe these experiences. Attitudes about their families are translated by children as attitudes toward themselves. Early childhood staff must pay close attention to both the overt and covert messages they send to children about the value and acceptability of all types of families. Ongoing discussion and activities that help children understand the ways in which all families are the same and all families are different serve as a major support to children's construction of their social identities and sense of value and worth.

FAMILY SYSTEMS THEORIES

Family systems theories refers to multiple perspectives on family interactions through the lens of the entire family. These approaches take into account the complexity of relationships within families. National standards for early childhood teacher preparation indicate that candidates for licensure should be well versed in many theories of child development and family studies, including family systems theories. However, Linda Garriss Christian noted a decade ago that family systems viewpoints are too rarely included as key factors in early childhood education. Still, little has changed in the United States in relation to the inclusion of systems understanding for partnerships with families. Just as deep knowledge of child development benefits early childhood teachers as they plan and implement developmentally appropriate practices in a classroom, it is believed that depth of understanding of family systems helps early childhood professionals to form reciprocal partnerships with diverse families. This entry describes three respected systems viewpoints: family life cycle, Bowen family systems theory, and Olson's circumplex model.

Family Life Cycle

Betty Carter and Monica McGoldrick describe a family life cycle perspective with a model that includes concentric circles representing the individual at the innermost circle. As a reader moves to the outermost circle, immediate family, extended family, local community, and larger society are represented. Arrows appear within the circles to indicate that each system impacts the others. One premise of this theory is that everything that affects one family member also affects other members, albeit not to the same degree. For example, when a couple has their first child, not only do they become parents, but their parents may become first-time grandparents or add a new grandchild, siblings may become aunts or uncles, and with these new titles, relationships are bound to be in flux.

In addition, this cyclic approach delineates two types of stressors that occur over time within families: horizontal and vertical. Horizontal stressors impact families over time and include both expected and unexpected events. Expected events include typical life cycle transitions such as marriage, birth of children, empty nest, and retirement. Examples of unpredictable events include effects of chronic illness or disability, climate disasters, and war. Vertical stressors are those that are passed down through the family, such as genetic outcomes, family values, rituals and practices, political views, addictions, oppression, and economic status.

Family life cycle approaches examine how families change over time. Relationships among family members, rather than family functions, are given priority. Intergenerational relationships have been shown to influence how families move from one stage of the life cycle, such as transitioning from a married couple to a family with a young child or children. In this example, grandparents' values and practices would be expected to influence new parents as they shift into parenting mode. It is not uncommon for new parents to view their role of mother or father along with their partner's role of mother or father differently from one another and based on experiences from their families of origin.

Although family life cycle perspectives indicate what may be viewed as a once-typical sequence of family change for middle-class families, proponents acknowledge that variations in a chain of events may change for culturally or economically diverse families. Carter and McGoldrick refer to the stage of family life with young children as the pressure-cooker phase of family due to increased demands on adults and constant nurturing needs of children. Early childhood teachers who are aware of this connotation may be able to empathize when young children come to school without lunch money or parents forget to bring diapers to child care.

Being successful at parenting requires many resources. It is easier to find a balance with young children when they are well, child care is reliable, and parents have job security and reliable transportation. Social resources such as supportive extended family and friendship networks also help

new parents to provide necessary nurturance and care for their children. When even one of these resources becomes problematic, such as a car needing repairs, it can lead to multiple stressors such as being late for work and a child missing a school field trip. When many or most of these resources are not available to new parents, their stress may skyrocket and affect responsibilities to their children. Teachers who have an understanding of a life cycle approach are likely to be less judgmental of families and to be willing to offer information about local resources.

Bowen Family Systems Theory

Psychiatrist Murray Bowen created the Bowen family systems theory, which includes eight interconnected concepts by applying a systems approach that integrates knowledge of human evolution and research on families. Bowen's theory views families as units with deep emotional ties and complex interactions so that one family member's functioning affects other members due to the emotional interdependence necessary to support cohesiveness of the unit.

Bowen has constructed eight concepts that are essential to understanding this theory of family systems.

Triangles. Three-person relationships are viewed as the smallest stable unit in that they can tolerate more tension than two-person relationships. However, as social science has shown, one person is always uncomfortable and working for change in the relationship. Shifts among the three people in the triangle are inevitable and create a dynamic that causes stress. Typically, one person is always making efforts to be either an insider or an outsider. Emotions are affected and when one is pushed to an outside position, depression may occur.

Differentiation of Self. Having a strong sense of self typically develops throughout childhood and adolescence within the family of origin. Differentiation of self can be viewed on a continuum with some weak, some strong, and many at points in

between. Individuals with less differentiation of self have more difficulty in stressful situations and are likely to have heightened anxiety leading to greater need for intensive dependence on other family members. When multiple family members have less differentiation of self, they are likely to have serious emotional difficulties.

Nuclear Family Emotional Process. When families experience extended periods of stress, at least one of four emotional processes will be set into motion. The four processes are (1) marital conflict, (2) dysfunction in one spouse, (3) impairment of a child, and (4) emotional distance. Family tension leads to marital conflict when spouses become anxious and focus on what is wrong with one another. Dysfunction in one spouse occurs when he or she is pressured by the other to behave and think in particular ways. To maintain harmony, the pressured spouse goes along to get along, which may lead to high anxiety that triggers a medical need. When a child is viewed by parents as impaired, their focus on this child leads to the child focusing on them and inhibits his or her process of differentiation. Children in such a circumstance are likely to act out or internalize tensions of the family and have difficulties in school and with friendships.

Family Projection Process. This process explains how parents project or transmit their emotional difficulties onto a child, causing a child to develop intense relationship sensitivities and become vulnerable to chronic anxiety. Three steps in this process are parent focuses on a child that is believed to be at risk, parent interprets the child's behavior as supporting the belief, and parent treats the child as if he or she has some form of disability. As a parent goes through these steps, the intensity of the parent's relationship with the child increases as he or she tries to remedy the child through extreme affirmation.

Multigenerational Transmission Process. This process is related to individual differentiation and relationships through generations of a family. Some of what is transmitted from one generation

to another is intentional, and some transmission such as emotional reactions and behavior is not conscious. Relationship patterns in nuclear families typically have at least one sibling with higher differentiation than the parents and one with lower differentiation. As these offspring select significant others, higher differentiation individuals are more likely to establish marriages that differ from parents and lower differentiation individuals are less likely to establish different relationships than their parents. And so it goes through many generations. While highly differentiated persons have strong nuclear families and contribute to society, those who are poorly differentiated often have chaos in family and other relationships.

Emotional Cutoff. All individuals have unresolved issues with their family members that they may attempt to remedy by physical or emotional disconnectedness. The danger of cutting off relationships with parenting figures and siblings is that a person then risks placing too many expectations on spouse, children, or friends to meet emotional needs. As with other family processes, highly differentiated individuals are able to resolve more of their family issues and maintain optimal emotional connections. Less differentiated persons are more likely to continue to have unresolved concerns in their family relationships.

Sibling Position. In this theory, birth order interacts with individual differentiation to create variations in family processes. Bowen believed that sibling positions are equally valued, but those who are firstborn are more likely to be leaders and younger siblings to be followers. Sibling positions of parents are also a consideration in family relationships in that youngest siblings who have parents who were both firstborn may experience expectations that would be different if both parents had been youngest in their nuclear families.

Societal Emotional Process. As with families, societal-level groups, such as workplaces and social networks, experience emotional systems

that influence behavior. Bowen hypothesizes that society experiences periods of progressivism and regressivism and that it is more difficult for parents to raise children in periods of regressivism as those societal factors such as growth in violent crime, increasing litigious attitudes, drug abuse epidemics, and more filings of bankruptcy foster more challenging behaviors in children and adolescents. An interesting argument that is posed within the concept of societal emotional processes is that during periods of regression, it is more constructive for persons to work on themselves and examine their own contributions to regression rather than to focus on the next generation to improve the world since changing the self is more probable than changing others.

Since Bowen's theory emphasizes emotional connectedness and isolation, it is frequently applied in therapeutic settings. Early childhood teachers do not have credentials to apply these concepts in the same way as therapists would, but increasing understanding of family systems in a more generalized way is conducive to creating supportive interactions with families.

Olson's Circumplex Model of Family Systems

David Olson's circumplex model has an extensive body of research in support of the primary concepts: flexibility, cohesion, and communication skills. As with Bowen's theory, the purpose of this model that describes family dynamics is for therapeutic intervention. Families with a balance of flexibility and cohesion within their systems have been shown to be more functional than those with too high or too low flexibility or cohesion.

Flexibility is defined through four dimensions: chaotic, flexible, structured, and rigid. The two mid-range dimensions, flexible and structured, are viewed as having a balance and the two extremes, chaotic and rigid, are seen as unbalanced. Four dimensions of cohesion are disengaged, separated, connected, and enmeshed. As with flexibility, the two mid-range dimensions, separated and connected, are noted as balanced and the two extreme,

disengaged and enmeshed, are rated as unbalanced. In Olson's perspective, communication is seen as a skill that is supportive of families as they make efforts to move toward greater functionality in both flexibility and cohesion. Effective communication efforts, such as respect for communication, an ability to listen, a concern for others, and sharing authentically about their own feelings, appear to be more successful for families who are balanced in their levels of flexibility and cohesion.

Measures of the flexibility and cohesion dimensions have led to classification of family systems in one of three ways: balanced families who have balance on both the flexibility and cohesion arrays; midrange families who have balance on one dimension and are extreme on the other; and extreme families who measure as extreme on both dimensions, flexibility (either too loose/chaotic or too rigid) and cohesion (either too close/enmeshed or too far apart/disengaged). Combinations of each of the three classifications of the two dimensions are as follows:

Balanced: flexibly separated, flexibly connected, structurally separated, structurally connected

Mid-range: Flexibly disengaged, flexibly enmeshed, structurally disengaged, structurally enmeshed, chaotically separated, chaotically connected, rigidly separated, rigidly connected

Extreme: Chaotically disengaged, chaotically enmeshed, rigidly disengaged, rigidly enmeshed

The dynamic nature of any given family system is an inherent part of understanding the circumplex model. As families move through various life cycle experiences, it is expected that behaviors that are identified as balanced will vary somewhat. For example, family cohesion is often higher when young children are in need of consistent nurturance and caregiving than when adolescents are becoming more independent and seeking their own identities. Further, families with young children often have routine schedules that are so tightly packed that there may be little room for flexibility within the system.

Early childhood professionals may be able to increase their understanding of family systems as they become familiar with concepts of the circumplex model. Teachers often find that applying the concepts to their own family experiences helps to elucidate the difference between balanced and unbalanced flexibility and cohesion. As with the other systems approaches in this entry, foundational understanding of these perspectives is believed to help professionals to form authentic, respectful, reciprocal relationships with families of the children that they teach. An increase in the knowledge about family systems can support empathy and decrease judgment in these relationships.

FAMILY-CENTERED PRACTICES

Family-centered practices guide interactions between practitioners and families of young children. The Division for Early Childhood (DEC) of the Council for Exceptional Children defines family-centered practices as those that treat families with dignity and respect; are individualized, flexible, and responsive to the unique circumstances of diverse families; provide families with complete and unbiased information to make informed decisions about the supports and services they want for their child and family; and promote family involvement in acting on their choices. Family-centered practices reflect a philosophy that recognizes family strengths and acknowledges the family as the most important influence on a young child's learning and development.

This entry presents the history and evolution of family-centered practices, describes federal policies that guide the provision of family-centered supports and services for young children with disabilities, identifies recommended family-centered practices in early intervention/early childhood special education, distinguishes family-centered from family engagement practices, and provides two examples to illustrate these distinctions.

History and Policy

The definition of family-centered practices in early intervention and early childhood special education evolved from the principles of family-centered care. Family-centered care practices were developed in the 1980s to guide provision of services and supports to children with special health care needs. In 1987, the Association for the Care of Children's Health (ACCH) published a list of key principles and accompanying descriptions of practices associated with family-centered care. Among the key principles was recognition that the family, not service systems and professionals, is the constant in the child's life. Emphasis was placed on actions taken to facilitate parent and professional collaboration in all aspects of care; to share unbiased and complete information with families; to

implement comprehensive policies and programs that offer families emotional and financial support; to recognize family strengths and respect different methods of coping; to understand and incorporate the developmental needs of children and families into health care services; to encourage and facilitate parent-to-parent support; and to design health care delivery systems to be flexible, accessible, and responsive to family needs.

Education of the Handicapped Act Amendments Part H/IDEA Part C

Publication of family-centered care practices coincided with passage of the Education of the Handicapped Act Amendments in 1986 (Public Law 99-457). This act established the Part H Program for Infants and Toddlers with Disabilities and offered funding to states to design and subsequently implement within 5 years a comprehensive, coordinated, multidisciplinary, interagency program of early intervention for infants and toddlers from birth to age 3 with disabilities and their families. Congress established Part H in part to enhance the capacity of families to meet their child's unique needs and included the requirement that services be guided by an individualized family service plan (IFSP).

The IFSP regulations emphasized the importance of gathering information from families about their concerns, priorities, and resources as these related to enhancing the development of their child. The intent was for practitioners to learn what families wanted for themselves and their children rather than practitioners making these decisions. Requirements associated with the Part H program and IFSP contributed significantly to adoption and adaptation of family-centered care practices in early intervention.

The Education of All Handicapped Children Act was reauthorized and renamed the Individuals with Disabilities Education Act (IDEA) in 1990. Part H was changed to Part C in 1998 following the 1997–1998 IDEA reauthorization. The 2004 reauthorization of IDEA is the current federal policy guiding implementation of family-centered practices in Part C early intervention programs.

Implementation of regulations continues to emphasize collaborations and partnerships between families and practitioners focused on gathering information about family concerns, priorities, and resources as these relate to supporting a child's development as well as the active engagement of families in each step of the early intervention process, from first contacts through transition planning. The IFSP includes both child and family outcomes with recognition that early intervention should be individualized for each child and family.

IDEA Part B Section 619 Preschool Grants Program

The Part B Section 619 Preschool Grants Program is another program provided under IDEA for young children with disabilities. Section 619 authorizes grants to states to deliver special education and related services for children ages 3 through 5 years. Although family-centered practices are not an explicit focus of the Section 619 regulations, family participation is required when developing the individualized education program and making decisions about a child's educational placements and services. States also have the option of extending implementation of the IFSP into preschool for children ages 3 to 5 years. This option acknowledges the importance and appropriateness of family-centered practices from birth through age 5.

Recommended Family-Centered Practices in Early Intervention and Early Childhood Special Education

DEC-recommended practices guide practitioner and family actions and interactions related to supporting the development and learning of young children from birth to age 5 with or at risk for developmental delays or disabilities. In 1993, DEC first developed and published a set of recommended practices for the field of early intervention/early childhood special education that included practices focused on family participation. The preamble to these recommended practices

acknowledged families were equal members in and could take part in all aspects of early intervention/early childhood special education. In the set of recommended practices published in 2014, there are nine family-centered practices. The practices are related to building partnerships with families; providing families with information to inform decision making; responding to family concerns, priorities, and changing circumstances; working together with families to develop and implement IFSPs; recognizing and building on family strengths to enhance family confidence and competence; assisting families to identify and utilize their own network of informal and formal resources and supports; sharing information about their child in the family's preferred language; helping families know and understand their rights; and encouraging interested families to engage in leadership and advocacy opportunities. These practices characterize a family-centered approach, which aims to enhance the capacity of families to support their child's learning and development and address their identified concerns, resources, and priorities.

Family Engagement

The National Association for the Education of Young Children (NAEYC) helps guide policy and practice in early childhood education for all children from birth through age 8. NAEYC uses the term *family engagement* to describe the role of families in early care and education. NAEYC defines family engagement as a partnership between families and early childhood education programs. Family engagement practices include family participation in decisions about their child's education, two-way communication between the school and family about both the individual child and the program, collaboration and exchange of knowledge through active family participation in school activities and teacher integration of information about children's families and communities into instruction, extension of learning activities from school to the home environment, family creation of a home learning environment that links

goals between school and home, and professional development for teachers related to implementation of family engagement practices.

Distinguishing Family-Centered and Family Engagement Practices

Family-centered practices include family engagement practices and there is overlap in some key practices, such as ongoing communication with families, collaboration and exchange of information and knowledge, and family participation in program activities. Family-centered practices extend beyond family engagement. They are distinguished by their explicit focus on both family and child outcomes that are prioritized by the family in partnership with practitioners. An important and explicit principle of family-centered practices is that the well-being of the family is linked to the well-being of the child. Supports and services for both are likely to have a greater impact on child development and learning than programs that focus exclusively on the child. Research has demonstrated positive outcomes for both families and children when practitioners use family-centered practices as intended.

Examples of Family-Centered and Family Engagement Practices in Action

The examples that follow are hypothetical but are based on the collective experiences of the authors as they have interacted with families. Jessica is an 18-month-old girl with developmental delays in speech, language, and feeding. She and her family receive home visits from a Part C early intervention provider two times per week. To inform the development and implementation of the IFSP for Jessica and her family, the early intervention provider and speech therapist talked with Jessica's parents to gather information about the family's routines and activities, specific concerns they had related to Jessica's development and her participation in routines and activities, and supports her parents felt they needed for Jessica or the family. Her mother shared that mealtimes were the most

difficult routine for them because Jessica often screamed and threw her food and because she had difficulty eating independently. Both parents expressed that helping Jessica communicate her wants and needs during mealtime was a more immediate priority for them than teaching her to eat independently because they wanted to increase enjoyment of mealtimes at home and eat out at restaurants without Jessica throwing her food. The providers worked with Jessica's parents to develop IFSP outcomes, goals, and strategies they could use to facilitate Jessica's communication during meals. This example reflects family-centered practices related to responding to families' concerns and priorities, working together with families to develop and implement IFSPs, and recognizing and building on family strengths to enhance their competence and confidence.

Devon is a 2-year-old boy who attends a full-day community-based child care center Monday through Friday. At the center, he often cries and falls to the floor when asked to transition from one activity to another, such as from playtime to snack or from snack to outdoor play. His teacher has discussed this behavior with Devon's parents, who report similar behavior at home, such as when they need Devon to transition from the house to his car seat or from the backyard to bath time. Both his teachers and Devon's parents agreed to gather information about Devon's behavior at school and at home to understand when, with whom, and why his challenging behavior might be occurring. His parents and teacher then met to share ideas about strategies they could use at home and school to address or prevent Devon's challenging behavior during transitions. They worked together to develop an individualized behavior support plan for Devon. His teacher has been sending home reports about Devon's progress in a daily home-school notebook that allows his parents to respond each day to the teacher's notes and share updates about progress at home. This example is consistent with family engagement practices related to two-way communication between school and home, extension of learning activities from school to home, and linking goals between school and home.

These practices are distinguished from family-centered practices because they are primarily focused on a child outcome, although some of the practices used in this example reflect family-centered practices.

FATHERS

Traditionally, in most cultures women have been charged with caring for young children, first in their own families and extended families, and later in organized, collective groups. Early childhood development theorists such as Johann Heinrich Pestalozzi and Friedrich Froebel recognized the important role of mothers in helping nurture and educate young children. In much of the 20th and 21st centuries, theories and research on the adult influence on young children has focused on mothers, such as Mary Ainsworth's strange situation experiment, and on the assumed natural role of women in caring for young children. Thus, anything to do with young children has focused on mothers and women caregivers.

As early childhood programs became popular in the 1960s, both to provide child care while women worked (partly as a result of an increase in single, female-headed households) and to provide compensatory education in programs such as Head Start, women were still viewed as the people to provide these programs. Beyond scholarship and practice, many people still view caring for young children as a natural role for women, and still view early childhood programs as the exclusive domain of women. This also includes father involvement in early childhood programs, which is much less than mother involvement. Even fathers who are active parents at home tend to be less involved in their child's early childhood programs.

Barriers

While most people in the early childhood field intellectually support father involvement in the lives of young children, both at home and in the early childhood program, many barriers prevent this from occurring. These barriers include

- the predominantly female nature of the early childhood field;
- the fact that, as a culture, we do not expect or support men to be actively involved in the lives

of their young children, at home and in the community; and

- more and more young children do not live with their biological fathers.

Female Nature of the Early Childhood Field

The female nature of the contemporary early childhood field is unquestionable. By itself, there is nothing wrong with this. However, it does pose issues for any efforts to actively include fathers and other men in early childhood programs. First, female teachers and providers are comfortable working with and communicating with mothers, partly because many are mothers themselves, and also because they are all women. While some women are comfortable working closely with men, many are more comfortable working with children and other women (which is one reason some people enter the field). Further, due to a long history of working closely with mothers, early childhood programs have developed effective methods, procedures, and techniques that support and enhance female-female communication and mutual support.

Men Often Not Expected to Be Involved With Their Young Children

In American culture, men's first priority has always been to provide for the family. While this is changing, men who do care for their young children cannot look to their own fathers as role models, and often do not receive support from people at work and close male friends. Thus they are often charting new territory, which can be psychologically and emotionally exhausting. Further, male colleagues and male social activities used in male bonding and brotherhood in the American culture—drinking, sports, home repair, and so on—do not naturally lend themselves to including young children. In some cases, male colleagues may even belittle a colleague's maleness who is involved with his children, and who may have to "take care of my daughter" instead of playing on the company baseball team.

Often the father's workplace does not support his involvement in addressing the daily needs of his children, such as doctor and dentist visits, parent-teacher conferences, and so on. This can be exhibited by tacit comments ("why is your wife not doing that?") and policies regarding bonuses and advancement ("he did not stay in the evenings to finish important projects"). These policies and attitudes can result in a lack of involvement by fathers in their child's early childhood program. Further, a man may be uncomfortable working with early childhood staff. Sometimes this might be a new role for him; certainly, the overall female nature of the program can be quite intimidating. Fathers who have friends who also have young children may provide moral support; those that do not may need extra help.

Children Without Biological Fathers in Their Lives

While more and more children do not live with their biological fathers, there are often other men actively involved in their lives—grandfathers, boyfriends, uncles, fathers of other children in the family, and male friends of the family. Early childhood programs need to proactively find a variety of constructive and positive ways to include these men in the program, barring legal or social complications. This can become quite messy, but programs need to find ways to extend father-involvement activities beyond traditional, biological fathers, to these men who are actively involved in the lives of young children. In this entry the word *father* is used to include any important male in the life of a young child.

Ways to Involve Fathers in Early Childhood Programs

There are many ways to involve fathers in early care and education programs that serve their children, including volunteering in the program or the classroom, being an official visitor to their child's classroom, being involved in group parenting education, and leading or participating in program-wide projects.

Volunteering in the Program

The goals for having fathers volunteer include

- to work together with staff for the welfare of the child,
- to learn parenting skills from other parents and program staff,
- to learn fun and educational activities that they can use with their children at home and in the community,
- to have their child feel special when they volunteer, and
- to be a healthy role model to both girls and boys in the program by positively impacting the program.

There are many things fathers can do in the program. They can help in the classroom by assisting in a reading activity, helping children learn woodworking skills, organizing physical games and activities on the playground, playing in the block area, and so on. One approach to volunteering in the program is called parent-child interaction time. In this scenario, the father engages in quality time with his child, rather than being involved in general activities or supervision in the classroom, on the playground, or on a fieldtrip. Sometimes the purpose of this activity is to just spend time together; on other occasions, it may revolve around a specific activity, such as reading a book together, doing a math activity or science experiment, or playing together. In this latter case the teacher assists the father in providing developmentally appropriate activities that can be copied, extended, and elaborated at home and in the community (e.g., in a library or museum).

Official Visitors to the Classroom/Program

Early childhood programs thrive on bringing community members to the classroom to present occupations, and to bring the community to the classroom. Programs should not forget that a great source for these classroom visitors is fathers of children in the program. In one program one of the fathers was a volunteer firefighter. He led the class

on a walk to the nearby fire station, where he showed them the equipment and how to use the fire hoses. The children had a great time putting on the equipment and climbing all over the fire engine. And the daughter of the firefighter was extremely proud of her father!

In another case, a father visited a writing class in an elementary school and showed the students the different books and articles he had published; and in a third example, a grandfather talked to the class about preparing for the school garden in the spring. One caution is not to give more importance to visits by certain kinds of fathers, such as members of professional sports teams. This adds little to the program or to the students' experiences.

Involving Men in Projects in the Program

One great way to involve fathers in a program is to create projects in which they can contribute their skills and passions. Many fathers are skilled in woodworking, construction, and other hands-on activities. Some are also experts in technology. Projects such as building and repairing the playground, remodeling the playground to be accessible, and developing a garden for the program can all work well. One program involved fathers who worked in a local wood factory to design and build a loft in one of the classrooms; another had fathers build puppet screens for every classroom in a large Head Start program. Several fathers in one program would collect clean, soft wood from local lumber stores to keep the woodworks areas supplied. And fathers were in charge of barbecuing the food for the parent picnic in a large, urban Head Start program. The secret of these projects is to find things men like to do and to give them a sense of responsibility.

Group Parent Education

Many early childhood programs provide group parenting education. One way a program can increase father involvement is to create a parenting group just for men—preferably led by a father. Goals for such programs include the following:

- Provide a safe environment for men to talk about parenting. Participants need to know they can express their ideas and concerns, and that different perspectives will be respected. The leader should make sure that all participants accept that whatever is said in the group stays in the group (unless it violates professional ethics). Often selecting a specific topic, such as typical development for different-age children, is a good, nonthreatening way to start the discussion. Also the leader should make sure each father, including those who are less assertive, participates in the discussion.
- Learn about childhood milestones and individual differences, including differences between girls and boys. It is very important for fathers to understand normal development, and be able to have normal expectations. They also need to understand individual differences in children.
- Discuss the challenges of contemporary fatherhood. As already stated, many fathers cannot look to their own fathers for role models; further, in different cultures, immigrant groups, and diverse families, there are different ideas of what father involvement should be. Many fathers also do not experience support from other men—their own fathers, siblings, and peers.
- For many men, discipline and control of their children are important issues; however, in too many cases, their ideas of punishment are ineffective and/or developmentally inappropriate. The leader of the group might want to bring a male expert—possibly of the same cultural background as the men in the group—to discuss appropriate ways fathers can demonstrate power and control with their children, while providing appropriate discipline and guidance.

Conclusion

Historically women have cared for young children—at home, in the community, and in organized early childhood programs. While today more fathers are actively involved with their young children, the early childhood field still focuses on

mother–child interactions, and few men are actively involved in their children’s early childhood programs. Despite barriers to involving men in early childhood programs, there are a variety of ways to include fathers in their children’s programs, including volunteering, official classroom visitors, projects, and group parenting education.

FATHERS IN EARLY INTERVENTION

Fathers in early intervention refers to fathers’ active participation in early intervention services for children who have been identified or are at risk for disabilities. This entry (a) discusses the importance of fathers’ involvement in early intervention, (b) delineates barriers to father involvement, and (c) highlights ways to encourage father involvement.

Overview

An ecological and ecocultural viewpoint provides a framework for recognizing the importance family and culture play in child development. Research demonstrates a positive relationship between parental involvement and children’s academic,

social, and emotional outcomes throughout children’s school years and beyond. Parental involvement is a protective factor for children with disabilities as well as children and youth from culturally diverse backgrounds and low-income families.

Recently, more attention has been given to father and father figure involvement in early education. Father involvement in early intervention contributes to a child’s cognitive development, communication skills, emotional regulation, functional skills, self-care, and social competence. Moreover, research indicates that children who grow up with actively involved fathers gain numerous benefits including (a) increased self-esteem, (b) better academic performance, and (c) healthier relationships with peers.

Family Systems

The importance of father involvement in early childhood education has gained increasing attention over the past two decades due in part to changing family systems. Typically, fathers have been viewed as the “breadwinners” while mothers have been viewed as the “caregivers.” As more mothers work outside the home, parenting responsibilities are changing (e.g., the stay-at-home dad). Modern fathers are caregivers, role models, disciplinarians, and teachers.

Barriers to Father Involvement

Sociologists and anthropologists posit that people are socialized to assume gender-based roles and occupations within a society. For example, historically, many societies place the responsibility of child-rearing on the mother, while the father is expected to work outside of the home. Industrialized societies began rejecting this parenting “agreement” as women began working more outside the home. In the United States, the number of stay-at-home fathers has increased steadily as the number of mothers assuming the role of primary breadwinner has increased.

Research about father involvement in early education often cites barriers that impede a father’s

involvement in early education. The most frequently cited barriers are paternal reluctance and competing commitments. Lack of awareness and negative attitudes by education providers are also mentioned in some of the literature. Other barriers to father involvement in early intervention include the following:

Female Environment. While gender roles and the influence of gender are evolving, early childhood education is still a predominantly female occupation. Consequently, fathers of young children receiving early intervention services are often the only males invited to participate in programming meetings. Unfortunately, some research indicates that fathers often feel that they encounter negative attitudes from school personnel when they are present in educational settings.

Cultural Considerations. Similar to other important aspects of early childhood education, barriers to father involvement in early intervention can only be understood and addressed when viewed through a cultural lens. Many cultures clearly assign the father as the spokesperson for all family matters, including early intervention programming. It should also be noted that some cultures prefer to restrict interactions between opposite genders.

Work Commitments. Just like mothers who work outside of the home, fathers who work outside the home are often limited in their ability to participate in early intervention programming and school. Much of the research about barriers to father involvement in early education points to fathers' work commitments as a major barrier to involvement.

Encouraging Fathers' Involvement

With the growing body of research suggesting the important role fathers play in their children's development, efforts are being pursued to involve fathers in early intervention programs. For example, programs can implement some relatively effortless practices, such as using the father's name on forms and communicating with fathers even if they do not live with their children.

It is critical that fathers are invited to participate in early intervention activities. Therefore, staff training and support services should focus on increasing father involvement. Specifically, staff must learn how to build relationships with fathers, establish communication, and listen to fathers' voices. Another key factor lies in identifying a male "champion" to provide passionate leadership. Studies show that fathers are more likely to participate when specific efforts are tailored to their interests. Additionally, mothers should be involved with the development of initiatives for fathers. Efforts should focus on reducing ambivalence to father involvement and creating an open environment of acceptance.

Conclusion

An environment that facilitates a culture of father involvement in early intervention must be created through a deliberate process. It is important to start slow and build upon program success. Moreover, staff and parents must be aware of their own biases and roles involving fathers in early intervention. It is essential that we create an environment where fathers feel welcome in order to support child development and success.

FIELD EXPERIENCES

In its 2010 standards for early childhood professional preparation programs, the National Association for the Education of Young Children (NAEYC) states that high-quality field experiences are key components of the professional preparation of early childhood professionals. Field experiences may include observations, practica, home visits, student teaching, or other planned opportunities provided by a teacher preparation program to support the professional development of preservice teachers.

Both early field experiences (e.g., observing, shadowing, or assisting early childhood professionals) and capstone field experiences (e.g., student teaching, internships) are often framed as sites in which preservice teachers apply and practice using the knowledge and skills learned in campus-based coursework and/or develop professional dispositions, attitudes, and expectations. NAEYC considers field experiences to be not only opportunities to apply and practice campus-based learning but also sites of important learning in their own right and authentic opportunities to assess professional growth in the areas outlined in its six core professional preparation standards: (1) promoting child development and learning; (2) building family and community relationships; (3) observing, documenting, and assessing to support young children and families; (4) using developmentally effective approaches to connect with children and families; (5) using content knowledge to build meaningful curriculum; and (6) becoming a professional.

Conceptualizations of Field Experiences

Kenneth Zeichner offers a framework for thinking about the design and implementation of field experiences. The three conceptualizations of field experiences in this framework are based in very different perspectives on learning to teach: learning to teach as increasingly skilled application of technical knowledge and strategies, learning to teach through apprenticeship, and teaching and learning to teach as ongoing inquiry. While not necessarily mutually exclusive, they are useful for examining the range of field experiences offered in early childhood professional preparation programs.

The dominant conception of field experience for many years has been informed by technical-rational theory, which frames teaching as the performance of a set of technical strategies and behavior. Field experiences informed by this theoretical perspective are conceptualized as sites in which knowledge, strategies, and skills learned in campus-based courses are to be enacted and refined in field sites until they can be performed with fidelity. Technical-rational theory and focus on teaching as technical performance are associated with field experiences designed to provide preservice teachers with access to children, time for practice, and feedback on performance. Preservice teachers' success in these field experiences is judged by how closely their performance approximates what was taught in associated coursework and dominant practices in the field site.

Social exchange and social learning theories inform a range of apprenticeship conceptions of field experiences. Field experiences informed by these theoretical perspectives are designed to provide the novice opportunities to acquire professional knowledge and skill from an experienced practitioner in exchange for work. The type and amount of work that the preservice professional might perform can vary based on the experience and skill of the mentor and the time that can be devoted to mentoring as well as the expectations of the preservice professional's campus-based teacher preparation program. The successful student in this form of field experiences is one who learns to

perform in ways that are consistent with those of his or her mentor while also meeting the expectations of the teacher preparation program.

A third conceptualization of field experiences is grounded in the assumption that teaching is not merely a technical skill or performance but is instead a reflective and intentional process based on ongoing inquiry, reflection, and professional decision making. Grounded in sociocultural and adult learning theories, inquiry-oriented field experiences place emphasis on posing and pursuing questions of practice, seeking and testing possible answers while drawing on knowledge and skills taught in campus-based coursework, the wisdom and skill of the experienced practitioners with whom they are placed and their own experiences, and growing funds of professional knowledge. Successful students in inquiry-oriented field experiences regularly engage in questioning, close examination, and critical reflection on the processes and outcomes of their experiences in the field.

While practice-oriented approaches may support the development of skilled performance, they do not provide opportunities for preservice professionals to grow as intentional and empowered professionals as called for in the NAEYC Standards for Early Childhood Professional Preparation Programs. Field experiences that are aligned with standards in early childhood education are best conceptualized as *learning* opportunities rather than merely *practice* opportunities.

Contexts of Field Experiences

Because early childhood education spans birth through age 8, field experiences must necessarily include sites serving infants, toddlers, and children in preschool through primary grades and their families. In a field committed to preparing professionals to serve diverse cultural, language, economic, and geographic populations with a range of physical, social, emotional, and cognitive needs and talents, field experiences must reflect diversity. And because early childhood education prepares professionals to work in settings administered under different auspices—including but not limited to

community and corporate center-based programs, family child care, public and private schools, inclusive and general education classrooms, early intervention programs, community agencies, and policy and advocacy work—field experiences must acknowledge this diversity as well.

The competing demands of providing field experiences across these many populations and sectors while maintaining standards of quality for field experiences are legion. The NAEYC Standards for Early Childhood Professional Preparation Programs acknowledge this reality and stipulate that when a particular site may represent some of the various diversities of the field but not meet all standards of quality for programs serving young children, its value might be judged in terms of the potential for supporting preservice teachers' development in each of the NAEYC professional preparation standards.

Structural and Process Indicators of Quality

When the structures and processes of field experiences are intentionally planned, thoughtfully sequenced, and supported by skilled mentors who engage students in reflection in order to make meaning of their experiences and to evaluate those experiences against standards of quality in early childhood education, the potential of a field experience for supporting preservice teachers' development in field experiences is increased.

Field experiences may be structured in ways that place preservice teachers alone or in partner placements in which two preservice teachers work together in the same site. Field experiences may be or may not be mediated by a supervisor from the teacher preparation program and, if so, the frequency and duration can vary. The work the preservice teachers do may be structured to provide increasing responsibility for parts of the program over the course of the placement and, in student teaching, culminating in solo teaching. Or early field experiences and capstone experiences may be structured following a co-teaching model in which mentor teachers and preservice teachers engage

together in curriculum planning and implementation from the outset.

Currently, there is little data available on the number and duration of field experiences required in early childhood education programs. However, in programs preparing teachers for elementary licensure, which includes teaching young children ages 5 through 8, it is common for teacher preparation programs to require several hundred hours of field experiences prior to student teaching. While in field experiences, the activities in which preservice teachers are invited or required to participate may be determined by the teacher preparation program, the host site, or a combination of both. The degree to which these activities match the developing competencies of the preservice teacher is critical.

The quality of mentoring, coaching, and other forms of support provided by campus-based early childhood professionals and field-based early childhood professionals are significant determinants of the quality of a field experience. Higher quality has been linked, for example, to specialized preparation in early childhood education, stipulated number of years of experience as a practitioner, and training in mentoring or coaching. The conceptualization of field experience largely determines the role and responsibilities of the campus-based and field-based professionals in any particular program, which might include hosting, monitoring, or mentoring the preservice student. In some cases, the campus-based and field-based professionals may be seen as sharing the role and responsibility of teacher educators.

Impact of Field Experiences

Teachers often report that field experiences were among the most important parts of their preparation. However, research on field experiences has yielded little causal evidence of the impact of specific characteristics of field experiences on teachers' pedagogical knowledge and skill and less on the impact on children's development and learning. There is, however, a more robust body of empirical research on the impact of field experiences on preservice teachers' beliefs and attitudes.

Current Critiques and Recommendations

Recent decades have brought increased attention to all aspects of teacher preparation. Critiques of the field experience have focused on the disconnect between campus-based learning and field-based learning and the privileging of academic knowledge over wisdom of practice. Field experiences conceptualized as "apply and practice" opportunities in which skills and knowledge taught in coursework are to be honed are most vulnerable to this criticism.

The National Council for Accreditation of Teacher Education (NCATE) Blue Ribbon Panel on Clinical Preparation and Partnerships for Improved Student Learning P-12 calls for grounding all of teacher preparation in field experiences in which academic knowledge and practitioner knowledge are intentionally linked throughout the teacher preparation program. Connecting learning across campus coursework and field experiences requires skilled professionals in both sites. However, clear and rigorous qualifications for both campus-based and field-based professionals have been found to be lacking. Specialized preparation and experience in the fields in which they are responsible for supporting preservice teachers are called for along with ongoing training in mentoring and coaching novice teachers.

Campus-based laboratory schools where content taught in coursework is demonstrated and students practice implementation and engaging in reflection and inquiry under the guidance of faculty and staff for whom teacher education is an official part of their identity and role provide sites with potential for close alignment of coursework and practical experience. Formal partnership agreements with field sites in which responsibility for teacher preparation is explicitly shared and accountability to all constituencies (the preservice teachers, the children they serve, and the field sites and teacher preparation programs) is a joint responsibility also may serve to reduce the gap and increase the quality of field experiences.

FOUNDATION FOR CHILD DEVELOPMENT

The Foundation for Child Development (FCD) is a private, independent foundation that supports research, fellowships, policy development, and

advocacy that enhance the physical, cognitive, social, and emotional development of young children. Its mission is to harness the power of research to ensure that all children benefit from early learning experiences that affirm their individual, family, and community assets; fortify them against harmful consequences arising from economic instability and social exclusion; and strengthen their developmental potential. For over 100 years, the Foundation for Child Development has used its resources to ensure that all families have the social and material capital they need to raise their children to be healthy, educated, and productive members of society.

FCD's History

The Foundation for Child Development was originally incorporated as a voluntary agency in New York in 1899 and established as the Association for the Aid of Crippled Children (AACC) in 1908. The primary function at that time was to provide assistance to children with physically handicapping conditions in New York City. Contributions from the public supported the work of AACC until 1944, when funds were received from the estate of Milo M. Belding in memory of his wife, Annie K. Belding, who had been a long-serving board member. The development of the polio vaccine led to a shift in the focus of AACC's work toward the study of birth defects, prenatal development, and mentally and emotionally handicapping conditions. In 1972 the Association for the Aid of Crippled Children changed its name to the Foundation for Child Development to better reflect its movement toward becoming an important grant-making institution that could support cutting-edge social research and advocacy on behalf of young children and their families. Eleven individuals have led AACC and FCD from 1908 to 2015: Mrs. E. C. Crawford; Miner C. Hill; Genevieve Wilson; Alice FitzGerald; Leonard W. Mayo; Robert J. Slater, Jr.; Orville G. Brim, Jr.; Barbara B. Blum; Ruby Takanishi; Deborah A. Phillips; and Jacqueline Jones.

FCD's Major Initiatives

Although FCD began its work as a public charity that was founded to address the physical disabilities of young children in New York City, it has evolved into a nationally prominent private foundation with a major emphasis on integrating research, policy, and advocacy that will enhance the lives of young children.

Research

Since its early history, the pursuit of scientific evidence has played a major role in the foundation's work. In 1913 the Association for the Aid of Crippled Children conducted a survey of a small area in the Cherry Hill section of New York City in order to better understand the care that young children with physical disabilities were receiving. The results revealed that most of the children with handicapping conditions were not receiving medical care. AACC was among the funders of the work of Dr. Robert Guthrie, whose research led to the introduction of the first newborn screening test in the United States for phenylketonuria (PKU) in the early 1960s. The disorder, if left untreated, could lead to mental retardation. AACC also supported research that enhanced understanding of the effects of malnutrition on children's development. In addition, over the years, the AACC has participated in other lobbies concerning child health and safety, including the development of legislation requiring seat belts and child restraint systems in vehicles. Support for rigorous scientific research and the linking of research to policy and practice remain central to the FCD mission.

Supporting Junior-Level Researchers

In the 1970s there was growing concern that the next generation of researchers needed to be cultivated. In 1974 the Foundation for Child Development collaborated with the W. T. Grant Foundation to begin a Congressional Science Fellows program, which allowed over 50 grantees to work with members of Congress and gain a deep understanding of the legislative processes that helps translate

knowledge into policy. In 1981 FCD initiated a Young Scholars Program (YSP), an annual competitive program that would provide support to early career researchers for scholarly development and research on the early learning and development of young children living in diverse and low-income families. The Young Scholars Program continues to provide support for junior scholars and enables them to develop research agendas that advance the understanding of child development, particularly in the context of poverty and social exclusion. Over the course of 10 years, FCD supported the work of a select group of junior scholars whose research was focused on the children of immigrant families. This rich body of work has informed the field and provided a deeper understanding of the health, social, emotional, and cognitive development of the rapidly increasing numbers of young children living in families that have migrated to the United States. The research provided information on how best to nurture, educate, and build on the resilience of these young children.

Child Well-Being Index (CWI)

From 1999 to 2013 the foundation funded the Child Well-Being Index (CWI), a measure that combined several sources of national data related to American children into one summary index. The CWI reflected the overall well-being of children in the United States and measured how trends in specific areas of well-being have changed each year since 1975.

PreK–3rd Education

Increased federal, state, and local funding of preschool programs led the Foundation for Child Development to take a closer look at the alignment of standards, curriculum, and assessment across the PreK to third-grade continuum. The transition from preschool to the formal K–12 environment was often seen as challenging for young children and their families, and there was inconsistent communication and professional collaboration between preschool and early elementary level teachers. The standards for preschool programs were often

separate from and unrelated to the state's K–12 standards; curriculum models and assessments were seldom integrated to those of the early elementary grades. In 2003 FCD began promoting a PreK–3 initiative that called for a seamless alignment of standards, curriculum, and assessment in programs serving children ages 3 to 8 years. The PreK–3 initiative proposed a fundamental restructuring of early education so that early care and education professionals across the preschool to third-grade continuum could work together to provide a continuity of services that would lead to a solid foundation for lifelong learning. FCD funded convenings of policy makers and practitioners to consider innovative ways of aligning preschool experiences with the early elementary system. In addition, the foundation provided funding for the National P–3 Center at the University of Washington and for the New America Foundation. These organizations were charged with advancing knowledge and understanding of effective preschool to third-grade strategies and their impact on teaching and learning.

Dual-Generation Programs

Realizing that children grow and develop in the context of their families and communities, the foundation supported a dual-generation/parent engagement initiative. The work was based on the theory that early learning experiences, such as high-quality preschool programs, can be most effective when they are implemented in conjunction with supports for the economic, psychological, and physical health of children's families.

New Directions

Entering its second century, the Foundation for Child Development continues to work in support of its mission to support the health and well-being of young children. However, by 2015 the early childhood landscape had changed dramatically with increased local, state, and federal investment in a variety of early learning programs. Under the Race to the Top—Early Learning Challenge competition, the federal government had invested approximately \$1 billion in funding to support

states in building stronger early care and education systems; every state had early learning standards for 4-year-olds; and localities such as San Antonio and Boston were making significant local investments in preschool programs. The city of New York was investing in and scaling up to a universal prekindergarten program with an articulated goal of providing full-day services to 70,000 4-year-olds. Yet, while the research demonstrated that high-quality programs could have a strong impact on children's growth and development, there was a paucity of evidence that identified the precise elements of these programs that were most effective, or not, for specific groups of children in well-defined contexts. As more early learning and development programs were funded, the research was not clear as to how the quality of the implementation of a specific early learning and development program and/or policy might vary by geographic areas at the national, state, or local levels. Therefore, FCD began 2015 by exploring how, as a foundation, it could best support research that focused on the implementation of early learning programs and advance a more nuanced understanding of why programs were effective, or not effective, for certain young children. FCD committed \$2 million to fund research that would support the New York City preschool initiative.

The foundation also acknowledged that a critical component of the successful implementation of early learning and development programs would be the early care and education professionals who carry out the programs. FCD's efforts turned to three potential workforce-related strategies: highlighting working conditions and compensation levels, improving the quality of instruction, and supporting the preparation and ongoing professional learning of early childhood teachers and leaders with emphasis on institutions of higher education. In 2015 the Institute of Medicine of the National Academies issued a report titled *Transforming the Workforce for Children Birth Through Age 8: A Unifying Foundation*. The report synthesized the science of early childhood development from birth through age 8, listed a set of competencies for early childhood educators, and made a total of 13 recommendations aimed at unifying the

professionals who work with children from birth through age 8. As FCD began to focus its resources on workforce-related issues, the report became a centerpiece for the foundation's efforts to move its vision and mission forward in a changing early care and education landscape.

FRAMEWORK OF SIX TYPES OF INVOLVEMENT

It is well documented that educators and parents have important roles to play in guiding young children's learning and success in school. Still, most preschools and elementary schools struggle to conduct effective programs that engage all families in their children's education. Through studies and fieldwork, researchers at Johns Hopkins University developed *School, Family, and Community Partnerships: Your Handbook for Action* that includes research-based approaches that enable schools at all grade levels to develop goal-linked programs of family and community engagement. (In this entry, the word *school* applies to early care

and education programs, formal preschools and kindergartens, and elementary schools that include preschool and primary grades.)

This entry summarizes *essential elements* that improve the quality of partnership programs from year to year. These include research-based structures and processes for organizing effective programs and a framework of six types of involvement for improving school plans and practices to engage all families in ways that contribute to student success, starting at the preschool level.

Essential Elements for Effective Partnership Programs

Studies are accumulating that confirm that, at every grade level, a good school has a challenging curriculum, useful assessments, and a program to engage parents in ways that improve student achievement, attendance, behavior, and other important school outcomes. This new direction changes parental involvement from an extra program—off to the side or left to chance—to an essential component of district and school organization, and a shared responsibility of educators, parents, and other community members.

Hundreds of schools across the country in the National Network of Partnership Schools (NNPS) based at Johns Hopkins University have helped identify specific structures and processes that are needed in goal-linked programs of family and community engagement at the preschool and early elementary levels. The following essential elements help educators, parents, and other family and community members work together to engage all families—not just a few—in students' early reading and math learning, and preparation for kindergarten. If any of the essentials are missing, they must be developed; if present, they can be continually strengthened. They are critical signposts on the path to partnerships.

Leadership. Preschool directors, school principals, and district superintendents strongly and publicly support the development of goal-linked programs of school, family, and community partnerships. A district or organizational leader for partnerships is

identified to promote a culture of partnerships across schools. A strategic plan stipulates that every school is expected to engage all of its students' families in age-appropriate activities that contribute to student learning and development.

Teamwork. Each school identifies an action team for partnerships (ATP) of teachers, parents, administrators, and other partners. The ATP's responsibility is to engage all families in planned activities. The ATP may check with or report to the school improvement team or school council to provide information on the quality and progress of the school's partnership program and to obtain advice or assistance.

One-Year Action Plans for Partnerships and the Framework of Six Types of Involvement. Each ATP writes an annual action plan for partnerships that selects, outlines, and schedules family and community involvement activities for six major types of involvement, which are outlined in the following section. Each year, the plan focuses activities on how family and community partners will help students attain two academic goals (e.g., improve early reading, math, or science skills), one nonacademic or behavioral goal (e.g., improve social behavior or attendance), and one overarching goal to create a welcoming partnership climate at the school.

Implementation of Planned Activities. Planned activities are implemented, challenges identified, and solutions devised to involve all families as partners in their children's education. Most engagement activities raise some challenges to reach families who were uninvolved or wary of the school or teachers. Although these have been referred to by some as "barriers" to partnerships, the challenges can be resolved with creative strategies, for example, to engage families who do not speak English, parents who are employed during the school day, fathers, or families who live at a distance or need transportation to school meetings. Over time, more families—indeed, all families—feel welcome and respected by teachers, contribute ideas, share leadership for the partnership program, and

become engaged in their children's education at school and at home.

Evaluation. The ATP assesses the quality of the school's partnership program each year and identifies challenges to address in the next school year. The ATP may assess progress on each of the essential elements; collect parents' requests for workshop topics; measure parent, student, and teacher satisfaction with the school; and examine other topics to improve the quality of the school's partnership program.

Funding. Adequate funding, preferably with a separate budget line, is essential for planned partnership activities. Practices may be supported by Title I and other federal programs, state and local funds, school and district accounts, PTA/PTO sponsorship, and community in-kind contributions. Partnership programs need not be costly. Some activities are cost-free, but financial support is needed for some activities in each year's action plan for partnerships.

Collegial Support. A school's partnership program thrives when the ATP has collegial support for partnerships from all teachers, school and district staff, parents, and community members. As a team continues to write annual plans, implement creative practices, and evaluate progress, colleagues will increase their understanding of and support for the school's partnership program.

Network Connections. Schools share best practices, raise questions, and solve challenges with other schools in the district, in a region, or across the country. Networking enables an ATP to continue to build knowledge, gather ideas, improve outreach to engage more families, and increase positive academic and behavioral results for students.

The eight essential elements combine to enable a school to plan, implement, evaluate, and continually improve its partnership program, even if school or district leaders change. The ATP is a key structure (replacing an individual who used to be assigned to "work with parents"), but ATP

members are not the only leaders of important engagement activities. A unified partnership program includes school-wide and grade-level activities planned by the ATP; activities of individual and grade-level teachers with their students' families; activities conducted by the PTA/PTO; and other business and community partnerships arranged by the principal or others at school. All family and community engagement activities contribute to the program of a partnership school.

Description of the Framework

In a series of studies, Joyce Epstein developed a framework of six major types of involvement that are separable, with characteristic practices and unique challenges, and that produce different results for students, parents, and teachers. The framework is not, itself, *the* partnership program. It is one of the essential elements of program development linked to the action plan for partnerships. The typology helps ATPs think systematically about how to engage family and community partners in different ways and different locations in goal-linked activities for student achievement and behavior. Because some parents cannot come often to meetings at the school building, the framework of six types of involvement revises expectations from "bodies in the school building" to two-way communications and collaborations at school, at home, or in the community. ATPs use the framework of six types of involvement with activities to do the following.

Type 1: Parenting. Assist families to understand child and adolescent development and establish home environments that support children as students at each age and grade level. Also, help educators to know their students' families and their goals and dreams for their children.

Type 2: Communicating. Communicate with families about school programs and student progress through effective school-to-home and home-to-school connections and technologies.

Type 3: Volunteering. Improve the recruitment, training, activities, and schedules to involve families

as volunteers and audiences at the school and in other locations to support school programs and student learning and activities.

Type 4: Learning at Home. Involve families with their children on homework, talent development, enrichment experiences, and other curriculum-linked activities and decisions.

Type 5: Decision Making. Include all families as participants in school decisions that affect their children and encourage their advocacy for their children. Ensure that parents with diverse backgrounds are leaders and representatives of all parents on school committees, councils, and in the PTA/PTO.

Type 6: Collaborating With the Community. Identify and integrate resources and services from businesses, agencies, and other groups in the community to strengthen and support the school, families, and student learning. Also, organize school and grade-level activities to benefit the community.

Sample Practical Applications of Framework

If a preschool or elementary school is working to increase students' reading readiness, for example, the ATP may activate the six types of involvement in its action plan for partnerships to engage all families with children on reading.

Sample Activities for the Six Types of Involvement to Improve Students' Reading Skills

Type 1—Parenting. Workshop(s) for parents on strategies to read picture books, books without words, and books in various languages at home with young children to strengthen the parent-child bond and to spark children's creativity.

Type 2—Communicating. Parent-teacher-student conferences on students' reading skills and progress, and next steps for parent and teacher to help the student attain or surpass grade-level reading standards.

Type 3—Volunteering. Recruitment and training of parent volunteers as reading buddies or literacy tutors for students who need extra help or practice on early reading, spelling, writing, and listening skills.

Type 4—Learning at Home. Weekly book bags with picture books that children take home for shared reading with a parent, including a laminated guide for parents to ask questions and lead discussions in the language of the home.

Type 5—Decision Making. Parent organization sponsors a book swap for students to exchange favorite books or a book fair for students and parents to purchase new books.

Type 6—Collaborating With the Community. Public librarian prepares summer reading lists by reading level for children, and summer story times for students and parents.

ATPs and other teachers may choose among hundreds of practices or design new and innovative activities for each type of involvement to encourage purposeful interactions of parents, educators, students, and others in the community. For example, there are many ways to use common and advanced technologies for teachers and parents to communicate with each other (Type 2); many ways to organize volunteers to assist educators, students, and families (Type 3); and so on. Each type of involvement requires two-way communications, so that educators and families exchange information and ideas and exercise their shared responsibilities for children's education. Many other family and community engagement activities with children on early reading, early math, and other academic and behavioral skills developed by preschools and elementary schools can be found in the annual *Promising Partnership Practices* reports published by NNPS and available at its website.

Conclusion

A review of research published by MDRC confirmed that parents with diverse backgrounds responded well to direct guidance and became

engaged with their children on literacy and numeracy readiness activities. Parents and children shared reading, had family conversations, practiced letters, counted, played with shapes, did money math and simple addition and subtraction, enjoyed creative dramatics, and conducted other activities. Children increased their reading, literacy, and numeracy skills, on average, more than did children in control or comparison groups whose parents were left on their own or without good guidance. Across studies, children with more engaged parents improved vocabulary, listening comprehension, rates of word reading, narrative storytelling, story comprehension, and reading and math achievement test scores.

Presently, parent and community engagement with children—even in the youngest grades—is mainly left to chance. It is clear that preschool, kindergarten, and early elementary teachers—indeed, educators at all grade levels—must reach out to intentionally engage parents with their children on basic literacy and math skills and school behaviors. With the essential elements and framework of six types of involvement discussed in this entry, every school can establish an equitable and effective program of school, family, and community partnerships to increase students' readiness for kindergarten and progress through the grades.

FREE PLAY, IMPORTANCE OF

A growing number of studies have documented the importance of play, with some research linking free or child-directed play to improvements in a child's ability to develop cognitive skills such as organization and long-term planning. But daily informal play appears to be on the decline in the United States based on numerous factors, including schools' focus on academic learning and efforts to improve test scores, parents' desire for structured activities for their children and concerns about safety, and the introduction of television, video games, and computers. In the United States, children's play has not been seen as a priority, as evidenced by the lack of play opportunities for many children. The United States is the only United Nations member state not to have ratified the 1989 United Nations Convention on the Rights

of the Child, which in Article 31 addresses the right to play.

There are many definitions of play, but they roughly fit into three categories: free or child-directed play, directed play, and highly directed play such as organized sports lessons.

Free play is a universal form, genetically programmed in each individual in what is assumed to be a biological drive of curiosity. This form of play stimulates children's capacity to learn and to develop basic skills and competencies through exploration and engagement with the world around them. In free play children activate their genetic inheritance as part of the earth's bio-system—the play environment of water, dirt, vegetation, and animals.

Directed play includes play where children engage in playful hands-on learning opportunities designed by an adult. The adult role is to work alongside children, to facilitate the activity, and to help create an outcome. Learning centers and projects in the classroom and hands-on activities at children's museums are good examples of this type of play. Traditional games such as jump rope, stickball, chanting games, and chasing games in a sense are a bridge between the free and directed types of play. They are a form of play with directive rules; however, the play is constantly being influenced by context and thus adapted by children themselves. Computer and video games fall into the directed play category.

Organized play and lessons are highly directed by adults. They include organized sports, games found in physical education, and lessons. Children's theater and activities organized by nonprofit or commercial organizations are also in this category. These settings limit and narrow the range of acceptable play responses.

All types of play are important, but free play is an essential need for a child's development. Several factors are evident in U.S. society that affect the future of free play and necessitate far stronger advocacy for play.

Continuing Poverty. More than one out of five children in the United States is living with inadequate provision for survival and development because of poverty and substandard living conditions. In some inner cities, conditions are very similar to those in third-world economies. Children are rearing younger children, performing manual labor, and begging for food rather than playing. Many children are forced to work at life-sustaining chores as soon as they are old enough to follow directions or to understand that if they don't work they will be beaten. Poverty forces children to be miniature adults during the early years. It robs a child's right to free play and presents an uncrossable barrier to other types of play opportunities as well.

Changing Cultural Values. In more affluent communities, there is often an indifference toward the importance of free play. Whereas children traditionally have been shielded from adult responsibilities and encouraged to play, now play is increasingly frowned on by parents who want their children to "learn" at the earliest possible moment. "Learning" means academics, including music or sports skills. Many parents overlook the social and emotional learning that come through play.

Changing School Agendas. Play opportunities have also been eliminated or reduced in many elementary schools across the nation. Recess and lunch "hour" are being sacrificed for increased academic time on task. Administrators and teachers, pressured to exhibit high standardized test scores, have eliminated play even though research shows that children have higher test scores when they have recess. Recess allows children to develop and nurture social and physical skills, and gives them opportunities to work out emotional responses in a setting with few adult restrictions.

In addition to eliminating or scaling back on recess, many elementary schools under-emphasize or negate playful learning opportunities indoors despite the research on how young children (birth to age 8) learn. Many schools have young children sit for long periods with paper and pencil tasks and working on rote memorization

exercises. Children learn through exploring, playing, manipulating, and interacting with their environment by touching and handling objects and materials in order to test their developing cognitive constructs against reality for optimal intellectual growth.

Inadequate Time. According to many sources, childhood and play are rapidly disappearing in the United States and other Western nations because weekly itineraries are jammed with a progression of homework, formal play opportunities, music lessons, Scout meetings, Little League, soccer, and dance lessons. There is not sufficient time to allow children to play informally, to just let them be children in their own space and time.

Increased Dependence on Screens. TV, smartphones, and computer and video games are now part of virtually every child's daily routine. Not only can children be adversely affected by what they view (adult violence, sexuality, language, commercials), but time spent passively watching TV and using technology could be time spent genuinely playing and interacting.

Inadequate Space. Children give life to neighborhoods, yet neighborhoods often have no place to play. Children growing up in high-density cities in apartment complexes have as little as 4 square meters of living and playing space per family. Research shows that the higher the floor of residential occupancy, the less children play. Even some suburban areas have few sidewalks and play spaces devoted to children. For many children walking or riding bikes to a friend's house to play is unsafe. Children need safe spaces close to home in which to play together and to be creative. It is a need that has not received sufficient priority in the development and redevelopment of all neighborhoods.

With play disappearing in the lives of today's children, there are much higher health and fitness risks throughout life than experienced by those children of past generations. Childhood obesity rates in the United States have risen dramatically since the 1970s, and 17% of children and adolescents ages 2 to 19 years old were considered obese

as of 2012. Children who are less active are also more susceptible to other serious health problems such as hypertension, diabetes, and psychological disorders.

Efforts are under way to ensure that more U.S. children have opportunities for free play. These include the work of the IPA/USA American Association for the Child's Right to Play, which among other strategies has promoted the restoration of school recess through preparing and distributing materials for parents and school administrators and has held media campaigns for recess and outdoor play.

FRIENDSHIPS

Friendships are dyadic relationships having six characteristics. They are reciprocal in that each child seeks friendship with the other. They represent preference in that the children seek time with each other rather than other available children.

They are caring relationships in that the children share an affective bond similar to (but less intense than) the bond shared with their parents. Friendships are enjoyable as evidenced by the positive emotions expressed by young friends together. They are a source of mutual support apparent in the frequent pro-social behavior that young children show toward their friends. Finally, friendships persist over time, with the friendships of young children lasting several weeks or months.

Within this definition, very early interaction exchanges among 1-year-olds may not qualify as friendships: Infants and many toddlers may pay attention to another child, imitate another child's behavior or vocalization, or play in complementary or reciprocal ways without forming lasting, mutual attachments. Indeed, conventional wisdom prior to the 1970s was that toddlers were not yet capable of initiating and maintaining friendships with same-age peers. In 2012, careful observations by Areana Eivers, Mara Brendgen, Frank Vitaro, and Anne Borge showed that some 2- and 3-year-olds did show preference, persistence, and mutual selection in peer relationships. Nevertheless, in their study, 24% of kindergarteners did not nominate any of their classmates as "friends you like to play with the most." Thus, a sizeable proportion of kindergarteners do not appear to engage in dyadic friendships.

Children's earliest friendships tend to be "convenience friendships" that occur when children are routinely available to each other as might occur within a day care setting or when children's families are close. Convenience friendships evidence the characteristics of true friendships: For example, 3-year-old Christine entered her day care center every morning, immediately searched for 3-year-old Michael, placed her train hat on Michael's head for the remainder of the day, and the two toddlers spent much of the day playing, eating, and working together. Their friendship lasted for 18 months until Christine moved to another city. Donna Wittmer, Sandra Petersen, and Margaret Puckett (2013) have suggested that the prevalence of convenience friendships may be shifting as more young children spend more time in out-of-home child care and so have more access to age peers.

Young children do not play exclusively with their convenience friend. Their choice of play partners can shift moment to moment if children are attracted away by more attractive games, and socially competent preschoolers must be adept at approaching and joining new groups of peers multiple times during a play period.

By early elementary grades, children transition into “barter friendships” characterized by a choreographed exchange of favors to and responsibilities for each other. Children in barter friendships recognize and track the reciprocity in their friendships. For example, Scott and Quique usually play together at recess, work together on group projects when the teacher allows them, visit each other’s home, and split the desserts from their lunch bags. Socially competent first graders understand that this exchange of favors represents a commitment to their friend, and the number and values of the favors must stay in approximate balance.

Although friendships can occur between people across ages, friendships with a same-age peer are particularly important to children’s development and the opportunities for growth are much greater. Eivers and colleagues (2012) elegantly describe preschool friends as “agents of mutual socialization” (p. 137). Given that both preschoolers in a friendship are social novices, they share responsibility for managing their friendship, communicating, initiating and shaping compromise, resolving conflicts, and coordinating their interactions. Thus, preschool friendships provide a stage within which children can practice essential social skills. Friendships are simultaneously a source of security for young children, allowing them to take risks and try out difficult tasks that they might not attempt alone. The reciprocity of friendships provides children with unique teachable moments when they take each other’s perspective and extend each other’s thinking and learning. This is evident in the children’s play: Carollee Howes (1996) and Wittmer and her colleagues (2013) have found that children’s play is more focused and successful when they play with friends; Gary Ladd (2005) refers to this as partner familiarity, and suggests that it facilitates play quality when children learn to anticipate

their friends’ interests, accommodate negotiated compromises, and predict likely responses.

The role of conflict in young friendships is a topic of much debate. Observational studies by Anne Sebanc (2003) suggest that considerable conflict occurs among preschool friends; this counter-intuitive finding may simply reflect the fact that preschool friends spend a great deal of time with each other and so have many opportunities for conflict. Many of the conflicts that occur are “conflicts of interest” in which one child’s preferences differ from those of the friend. When asked, 5-year-olds state that children should compromise when their interests conflict with their friends’ and explain that they would give priority to friends’ preferences over their own. Still, acting upon a compromise is much more difficult than saying that one should do so, and these conflicting findings may simply reflect the challenge young children face in acting upon their principles.

Sebanc (2003) and Engle and colleagues (2011) report that high levels of conflict in preschool friendships are associated with higher rates of aggression and peer rejection. However, Wittmer and her colleagues (2013) describe peer conflicts as opportunities for reduction of egocentrism; children who never experience conflicts with friends would never encounter differences that prompt them to perspective-take or reconcile.

Taken together, the research suggests that adults are far more likely to underestimate than overestimate very young children’s capacity for peer friendships. Children are more likely to form and benefit from mutual friendships when they have multiple, rich opportunities to play together with age mates. Having fun together is the nourishment that feeds young friendships and prompts children into higher-quality play with familiar play partners. Adults can contribute to emerging friendships by coaching young children in managing the conflicts of interest that will inevitably arise, and by using the friendships to further children’s mutual learning and development.

FUNDS OF KNOWLEDGE

Sociocultural theories explain ways that humans participate intently in informal family, community, and cultural activities and practices; learn naturally through these; and construct multiple identities. Diversity of, and within, families and cultures is now a global theme. Adopting culturally sensitive and equitable approaches and constructs to guide the education of children from diverse backgrounds is therefore vital.

Funds of knowledge is an empowering construct developed as an early example of culturally responsive pedagogy. Previously, responses to educational achievement lags by ethnic minority children had taken on a deficit approach based on an assumption that the poor quality of these children's home experiences meant they were not able to manage the demands of academic learning. Instead, funds of knowledge approaches explore the rich knowledge and lived experiences of families and cultures that can be drawn on in educational settings to enhance learning. It is therefore a concept of potential value to early childhood education where partnerships between families and educators are strongly promoted. The concept is dynamic, as it changes with each relationship in each family and evolves to new circumstances and cultures. Funds of knowledge can be considered as a theoretical, methodological, and pedagogical tool.

Funds of Knowledge: A Theoretical Tool

The original funds of knowledge research project was led by Norma González, Luis Moll, and Cathy Amanti. It was a partnership between academic and teacher-researchers that explored languages and literacy practices in everyday household activities in bilingual Mexican–Latino communities in Arizona in order to improve primary (elementary) education and student outcomes. A focus on funds of knowledge provides a framework to recognize ways children's knowledge is stimulated by, and arises in, the contexts of their intent participation in everyday activities and experiences. The knowledge and life experience encompassed in this is valued and drawn on in education.

Funds of knowledge were defined as the bodies of knowledge, including information, skills, and strategies, which underlie household functioning, development, and well-being. These included ways of thinking, approaches to learning, and practical skills. For example, children might regularly observe a parent writing a shopping list or reading a recipe. In this way, children gradually develop

early knowledge of literacy embedded in specific family routines and practices. Literacy has continued to be a focus of much work since this original study, but funds of knowledge has also been extended to other subject domains such as history, geography, mathematics, and science. Subsequent research has also considered wider influences of family and community members, such as siblings, friends, grandparents, and teachers.

One criticism of this original work was that the voices and experiences of children and families were reported through teacher interpretation rather than heard directly. Incorporating children's and families' perspectives strengthens the validity of the notion and highlights the pedagogical relationships in which funds of knowledge are developed. Studies that have extended use of the term into early childhood education have emphasized incorporating these perspectives and valuing the funds of knowledge children learn from relationships with peers. Mari Riojas-Cortez's project studied the sociodramatic play of 4- to 5-year-olds in a bilingual program to explore ways that culturally inclusive curriculum could be developed. This work included categories of cultural traits such as parents' language, values, and beliefs; ways of discipline; and the value of education as funds of knowledge. Funds of knowledge has further been used to explain children's interests, account for peers and other adults beyond family members, and identify decisions teachers made in choosing whose and which interests would be selected to create curriculum.

Funds of Knowledge: A Methodological Tool

In the original project, teacher-researchers visited the homes of two or three primary school-age students, and sometimes related community settings, up to three times to gather information about the knowledge families used in their daily lives and the job histories and everyday household practices of families. A funds of knowledge perspective shifts the balance of power toward families as experts while the visiting/interviewing teacher-researchers are positioned as learners. As Norma

González recounts, examples of household activities and routines in which children were involved included

car repair, gardening, home improvement, child-care, or working in a family business or hobby. . . . We asked about music practices, sports, shopping with coupons, and other aspects of a child's life, which helped us develop a composite and multi-dimensional image of the range of possible funds of knowledge. (González et al., 2005, p. 13)

Both the concept of funds of knowledge and the concept of being a teacher-researcher positioned these teachers as agents of change who could then empower all families to participate more deeply in their child's education. A further aspect of the methodology was that teachers shared their findings with each other during study groups. Dialogue between the teachers was identified as important to the success of the project in conceptualizing the connection between households and schools.

The family visits that occurred in Helen Hedges and Maria Cooper's project in early childhood education proved very powerful, including in ways unanticipated by the academic and teacher-researchers' expectations about deepening understandings and making connections across contexts. The visits were transformational by challenging assumptions teachers had (for example, about families and the languages that they spoke), making invisible barriers about communication and understandings explicit and enhancing parent-led communication with the centers.

Funds of Knowledge: A Pedagogical Tool

The pedagogical goal of a funds of knowledge approach is to recognize and incorporate family-based knowledge and expertise in educational settings in order to improve outcomes for diverse children. Marla Hensley was one of the teachers involved in the original funds of knowledge project. During a home visit she discovered that a father played guitar and keyboard and wrote songs and poetry. She asked the father to write

some children's songs and create a musical. Another parent she visited had a background in dance and was asked to help choreograph the musical. Several other parents participated in costume-making workshops. The musical was performed by children five times.

Within play-based early childhood settings, funds of knowledge may be an important way in which children's interests can be recognized, engaged with, and extended. For one set of teacher-researchers in Helen Hedges and Maria Cooper's project the experience of visiting several apartments and shared living spaces prompted changes to the layout of the center. Teachers adapted the previously open plan learning and teaching environment layout to smaller spaces with smaller numbers of play resources to reflect the apartment-style living and shared family spaces. In addition, they invited parent expertise as a contribution to the curriculum: One mother was invited to share her artistic knowledge with children. The teachers at this center found also that they began to reduce a reliance on documentation practices to build relationships, favoring interpersonal approaches instead.

Issues and Developments Related to Funds of Knowledge

Funds of knowledge has been critiqued as a loose notion as it tends to blur the content, sources, and processes of the related learning. However, this may be appealing in early childhood education because the ways that children learn and what they learn are often incorporated together in the form of holistic outcomes. It has also been critiqued as having the potential to essentialize and stereotype cultures unless situated clearly within participatory learning and repertoires of practice framings. Further, families may not be the primary sources of funds of knowledge beyond a certain age when children participate in peer groups and gain access to popular culture and social media sources that introduce alternate kinds and sources of knowledge.

Within early childhood education, there may not always be a straightforward connection

between family activities and practices and children's interests as enacted in a center. For example, as funds of knowledge are embedded in everyday cultural practices, and are implicit, they can be hard to recognize and articulate by parents. Alongside visits, teachers may need to engage in follow-up conversations, ask more probing questions, and/or observe carefully to reveal the funds of knowledge influences.

Funds of knowledge is also not a panacea to addressing diversity and cultural responsiveness, as teachers may still face dilemmas about whether to value or how to recognize and respond to "dark" funds of knowledge such as bullying behaviors. In addition, funds of knowledge may appear to incorporate some gendered beliefs and practices, which may create dilemmas for teachers. Nevertheless, some authors have argued for ways these beliefs and practices might be used beneficially in classroom conversations to debate what and whose knowledge might be legitimated. Therefore a funds of knowledge framing should not be accepted *ipso facto* without accompanying critical thinking.

In addition, while the purpose of funds of knowledge was to use this knowledge to scaffold new learning in the classroom, not just acknowledge and/or replicate it, a clear explanation is yet to be made between this intuitive type of knowledge and conceptual knowledge developed later in formal schooling. Elizabeth Moje and other scholars began to address this through the use of hybridity theory and the notion of "third space," concepts where dialectically opposing ideas can begin to generate new relationships and creative connections.

More recently, funds of knowledge has contributed a new dimension to theories of human identity formation. The term "funds of identity" has been appropriated to explore the range of family and cultural knowledge, beliefs, and practices that contribute to self-knowledge and understandings.

Conclusion

Funds of knowledge has developed over time as a term to include economic, social, linguistic, and cultural capital held by individuals, families, and

groups. Funds of knowledge are cultural resources that can support teachers' understanding of the dynamic nature of children's lives within their families and cultures, and enable teachers to utilize the knowledge gained about communities within educational settings. A funds of knowledge approach has the potential to transform early childhood learning and teaching environments and implement partnerships with families, communities, and cultures authentically. However, it ought not to be adopted uncritically but instead contribute to the range and types of knowledge and evidence that teachers bring to their curricular and pedagogical decision making.

G

GENDER DIVERSITY

There are two issues related to gender diversity in early childhood: young children's development of gender identity and gender identity of practicing early childhood professionals.

Gender Identity

Acquiring gender identity is complex. Many different sources are involved in helping us understand what it means to be male or female—a man or a woman. Young children are strongly influenced by significant adults in their lives: mothers, fathers, siblings, grandparents, extended family members, caregivers, teachers, guardians, and neighbors. They are also shaped by forces in society and affected by media and culture. These are considered environmental influences, and teach us what to expect about our behavior as females or males. Gender identity also includes our anatomy that defines us through our physical make-up or biology. Young children develop some kind of gender identity as early as age 2 years, although even as preschoolers they do not yet clearly understand what makes them male or female, and they tend to focus on physical appearance or typical or atypical behaviors. For example, if a boy has long hair, his peers might call him “a girl.” And some little girls are considered to be “like boys” if they play in the large-block area wearing a hard hat.

The ways in which teachers interact with girls and boys are connected to their own experiences with gender identity. Gender identity affects their interactions with children in their care and is connected to feelings of self-worth and self-perception, notions about sexuality, and even fears of intimacy. Indeed, gender identity exposes people to their deepest shadows and vulnerabilities. It is at the very core of our being, the foundation of who we are, and how we interact with the world—personally and professionally. Gender identity affects a person's worldview and is directly related to feelings of empowerment or powerlessness. Teachers might convey ambiguity to young children in subtle, unconscious ways. For example, is a particular teacher really comfortable with girls playing in the large-block corner, wearing hard hats and shouting out raucously? Or does that teacher feel the need to shush them or even redirect their play to something quieter, and more feminine? Does a teacher feel comfortable when little boys cry or need support, or does that teacher subtly encourage them to hold back their emotional expression?

Where do early childhood professionals begin to think about how they developed their identity? They might start by thinking about how significant adults in their lives influenced their development in the earliest years, and helped them shape their identity as a woman or a man. Here are some additional questions to help us think about how we acquired our gender identity:

“How did I learn about becoming a woman/man?

What are my earliest memories?

What was fun or painful for me as I learned about these aspects of my identity?

How do I agree or disagree with my parents’ or guardians’ ideas about gender?

If I disagree, how did I develop my own ideas?

What and who were significant influences on me?

If I am a parent or plan to become one, what would I want to teach my own children about gender identity?

What type of stereotypes would I want to avoid?

Which aspects would I want to embrace?”

(Jacobson, 2010, p. 11)

When teachers enter the classroom, they bring with them the personal feelings, early childhood memories, prejudices, values, beliefs, and attitudes that have shaped who they are.

Influence of Media and Culture

Children’s books contribute to, usually unconsciously, reinforcing gender-biased roles of our society. Male heroes are typically adventurous and courageous, solve problems, and are allowed or expected to be naughty or mischievous. Female roles are nurturing. They typically take care of others, cook, clean, and behave in gentle and cute ways. Whether the characters in the children’s books are children themselves or little furry animals like rabbits, kittens, or puppies, the gender roles are usually clear. Children can be taught to become more aware that perceptions and biases are learned through direct and subtle messages within our culture and society. Sharing a different point of view or allowing discussions with diverse opinions challenges us to develop different perceptions. Observing, analyzing, and discussing with others can develop awareness about gender stereotyping. For example, a trip to a toy store is a good way to observe what society informs us about gender stereotypes. Is the girl toy aisle full of the color pink, with dolls and kitchen sets?

Does the boy aisle contain adventurous toys with dark greens, blues, and blacks? A related question is, How do families relate to girl or boy babies?

In addition, there is a growing concern in the field of early childhood education about the “sexualization of childhood” (Derman-Sparks & Edwards, 2010, p. 96), where instead of young children developing their sexual identity gradually and appropriately, they are being greatly influenced by media and popular culture with “graphic sexual images,” where “girls learn that their value is determined by how ‘sexy’ they look, rather than who they are and what they achieve” (p. 96). Boys, on the other hand, learn to not only judge girls by these standards but “judge themselves and each other by how strong and independent they seem—and how ready they are to fight” (p. 96).

Teachers of young children can facilitate discussion or offer different options to counter-balance messages from media and society. Early childhood professionals do this best by developing awareness about these stereotypes themselves.

Gender Diversity and the Early Childhood Profession

Early childhood teachers in child care settings work long, hard hours and are the lowest paid people in the education profession. Most of society views caregivers as just a bunch of women watching a bunch of kids. Some states are realizing the importance of education in the early years by funding and reinforcing prekindergarten programs for 4-year-olds. However, most often they still do not include infant, toddler, and 3-year-old care and education as important enough to require caregivers a quality education or, consequently, a decent living wage. Therefore, teachers and caregivers often feel powerless and under-appreciated from the lack of respect from society for the work that they do.

There are very few men who choose a nurturing profession like child care and education. In fact, men make up about only 20% of the teaching profession. There are a number of theories as to why men are a minority in the early childhood profession. One of the reasons is that child care teachers

are underpaid and most men would not choose a profession that pays so poorly. Some even consider that if more men joined the profession it would raise the status of early childhood education, and then women and men would receive better pay, because society still views female-dominated professions as having less value. Men who choose to stay in the profession often prefer to take more prestigious administrative positions, where the pay is higher than classroom teaching.

Another theory is that society stigmatizes men who choose a profession caring for children. Even today, taking care of young children is seen as a predominantly female profession. In many cases in the United States, families are wary of men caring for their youngest children, fearing that men are more likely to sexually abuse them. These are prejudices and stereotypes. Some of their female counterparts still believe that women better serve early childhood education, because they consider men unable to be nurturing or patient enough to work with young children. Men who work in the early childhood profession suffer discrimination as any cultural minority. Some people believe that men who choose the early childhood profession must be gay. This is yet one more prejudice or stereotype because, in fact, men who work with young children are as diverse a group as their female counterparts or any other group of men.

Gender diversity is a complex subject, and a product of a patriarchal model of society, affecting men and women alike. This is a model based on relationships of competition and dominance, where predominantly White men's views "guide the beliefs and structures that cement the dominant culture" (Jacobson, 2003, p. 25). The work for early childhood teachers is to be activists for changing this model to one with relationships of interdependence and equity, where girls and boys can develop as whole human beings with an identity that is suited to who they are.

GENDER ROLES

Gender roles are the behaviors, interests, attitudes, and skills that a society or culture considers "appropriate" for females and males. Gender roles are important to understand because they are based on social norms or shared rules about what women and men should do, how girls and boys should act, or what are considered "normal" forms of femininity and masculinity. For example, women are often assumed to be well suited for early childhood teaching because they will bring with them caring attitudes, an understanding of emotions, and other feminized qualities. Or out in

the playground it is often thought that boys will take part in rough-and-tumble play and girls will want to play quieter and less active games. This entry examines how gender roles are explained, raises questions about these theories, and highlights the politics of role modeling.

All societies have gender roles and everyone grows up gendered, even if the content and expectation of these roles in different places and times may vary significantly. Gender roles are related to how families function, how children experience education, how teachers interpret children's behaviors, and the way people present and see themselves in their communities. Everyone belongs to several communities and these can include families, churches, schools, classrooms, and playgrounds. Parents, grandparents, siblings, teachers, teaching assistants, librarians, friends, and even young children are considered to be members of these different communities and take part in enforcing gender roles.

Sex and Gender

Sex and gender are two taken-for-granted concepts that are related to gender roles. Social learning theory is often used to explain sex and gender. This theory assumes that everyone is first born with a sex and then learns how to be gendered. Sex most often refers to biological differences, such as chromosomes, hormones, and internal and external sex organs. Gender, on the other hand, describes the characteristics that a society or culture assigns to the categories of femininity and masculinity and what are considered to be appropriate feminine or masculine behaviors.

Social learning theory is based on observable behaviors. From this perspective, children acquire gender roles by watching others and then imitating models of gender behaviors that they see and value in their lives. Their behaviors are then reinforced when people they trust and respect reprimand and reward their gendered behaviors.

This understanding of sex and gender is popular and easy to understand, but it has been questioned because it positions sex as a biological fact that is universal across all societies and cultures. It

assumes that everyone is born with either male or female sex organs, which is based on unquestioned conventions about an absolute biological division between male and female. This view also fails to account for intersexed or indeterminately gendered people. Although this perspective about sex and gender is easy to understand, it tends to perpetuate gender stereotypes because it presents the binary gender roles as neutral and natural. This explanation of sex and gender is unable to explain why masculine gender roles are consistently privileged over female gender roles.

Sociological Explanations of Gender Roles

Sociology has contributed to understanding gender roles within society. Sociological explanations of gender roles are guided by four theoretical perspectives: functionalism, social conflict theory, interactionist theory, and feminism. These different perspectives vary according to the level of analysis they use to understand gender roles. A macro-sociological analysis focuses on large-scale social phenomena, such as educational trends that are differentiated according to gender roles or the feminization of the early childhood workforce. A micro-sociological analysis attends to the daily interactions between genders, such as how girls regulate what it means to be "cool" or "pretty," or how children treat others who challenge gender stereotypes or engage in cross-gender behaviors on a regular basis. Some of the sociological research on gender roles attempts to bring together both a macro- and micro-analysis to understand how these roles are constructed, maintained, and challenged.

Sociological research on gender roles initially began by examining the sociology of the family and focused on the gendered roles of fathers, mothers, husbands, and wives. More recent sociological research on gender roles attends to gender and family relations across diverse families, such as dual-income-earning families, single-parent families, families from different social and cultural backgrounds, and gay and lesbian families.

Functionalism

Functionalism is a macro-sociological perspective that sees society being made up of different parts that depend on each other. Each of these parts contributes to the functioning of the whole society. This view focuses on how gender roles contribute to the social order or stability within the family. Although this theory was dominant in the mid-20th century, it is no longer considered a sufficient interpretation of the complexity of gender roles for most people.

Social Conflict Theory

This theory proposes that social order is preserved involuntarily through the exercise of power that some social groups hold over another. It analyzes gender roles from a macro-sociological view by attending to economic resources and how they function to give men more power and how these inequalities may promote subservience among women or neglect of issues that currently impact most on women, such as childbirth or domestic labor. This theory asserts that social structures are based on the dominance of some groups (males, husbands, fathers, paid workers, parents) over others (females, wives, mothers, unpaid workers, children). Conflict theory pays attention to the functions of social groups and how they regulate gender roles.

Interactionist Theory

This perspective focuses on micro-sociological views of gender as a social construction and how people “do” gender in everyday life. There has been much research in early childhood classrooms and playgrounds drawing from this theory. Children appear to be learning gender roles most intensively between the ages of 3 and 8, especially through their play. This research shows young children agentic about gender. That is, they perform stereotypical gender roles and gain pleasure from these gender performances. Research shows children as young as 3 years of age working hard to maintain female and male categories. At the same time, they also contest stereotypical gender

roles even though individuals and institutions are regulating them. This research raises questions about social learning theory because it challenges the notion that young children are passively soaking up what they see and then simply role modeling these behaviors. Instead, it highlights how young children take an active part maintaining and resisting gender roles.

Feminism

Sociological research conducted from a feminist perspective brings together micro and macro analysis to understand the impact gender has on everyday relationships and how this plays out in institutions. Most important, it highlights gender bias in society. A significant contribution that the feminist perspective has brought to sociological research on gender roles are the multiple oppressions that people face due to gender, race, and social class. This initial attention to the gender-race-social class link now makes it possible to locate other sites of oppression such as religion, sexuality, age, or disability. Feminist sociology advocates that research about gender roles must take into account the ways in which gender intersects with other social identities.

Moving From Gender Roles to Gender Relations

Most discussions about gender roles emphasize a dichotomy or division between male and female roles. This dichotomy begins with the presumed biological divide between male and female. This difference is then solidified when gender is defined as the social differences that either correspond to that divide, build on that divide, or are caused by that divide.

Basing gender roles on a dichotomy is problematic because it fails to draw attention to the significant differences within any group of women or men, girls or boys. This logic of gender roles is unable to explain the conflicts and the pleasures of those who define themselves outside the traditional and stereotypical masculine and female roles. Furthermore, it also does not allow for the

fact that gender, which is largely cultural, may be much more mutable than body morphology would suggest. Thus, there may not be only two genders, but three, or perhaps many more. Indeed some scholars already consider there to be multiple gender categories, such as differences around sexual desire (e.g., a lesbian-identified person may not be the same gender as a heterosexually identified female-bodied person) or the many permutations of transgender identities.

In the social sciences, there has been a move away from understanding gender as difference or through roles, toward focusing on gender relations. This shift makes it possible to think differently and critically about gender roles and the ways in which this logic promotes stereotypes. Not all gender relations are direct interactions between females and males. Gender relations may be mediated by technology, such as the Internet, and they happen between females and between males.

Gender relations carries with it the idea that rather than embodying or doing a fixed gender role, people may move in and out of diverse situations, which will allow for different kinds of gender relations. Consider, for example, the various gendered relations a boy might experience when cooking with his aunt and when engaging in rough-and-tumble play with same-age peers. Although in both instances the boy may be considered unproblematically male, the gender role he is taking up when seen by an outsider would look very different across these two circumstances.

The Politics of Role Modeling

Shifting from focusing on gender roles to gender relations is difficult to do because the common-sense logic used to understand the relationship between sex and gender dominates much of how society thinks about femininity and masculinity. In addition, how gender roles are acquired through a set of complex social processes that are linked to lifestyles, values, and expectations of particular social groups cannot be easily collapsed into two simple gender roles. Instead, people get a feel for the gender game from the cultures and communities they grow up in and the diverse

range of people and relationships of which they are a part. Children experience these relations in early childhood settings. Concentrating on gender relations requires complex thinking and involves unpacking the politics of role modeling.

One of the interesting ways in which role modeling has been used in early childhood education is related to increasing the number of males in the profession. The claim is that in such a feminized field of teaching, boys need different kinds of role models in their lives, such as male teachers. This discourse of role modeling fails to address the damaging effects of reducing gender identity to normative gender roles. It denies any consideration of how stereotypical gender roles maintain racism, sexism, heterosexism, and homophobia and how these impact teachers' identities, practices, and pedagogical relations with children.

This call for increasing male teachers is political because not only does it rely on a role-modeling discourse, but at the same time early childhood male teachers are mistrusted because of normative gender roles. This mistrust is a form of sexism against men and women. The greater the fear of men in caring for young children, the more common it is to move men out of directly caring for young children and into administrative roles. Not only does this reinforce the stereotype that men are thinkers and women are carers, but this then leaves the women to shoulder the "real" work of early childhood education.

Common-sense understandings of gender roles dominate how society thinks about femininity and masculinity. Since the logic of role-modeling is limited in its capacities to account for the complex dynamics of gender and power, it is important to embrace a range of theories for making links between micro and macro forces at play in people's thinking about gender roles and to understand gender relations. By questioning what we know about gender roles and how we know gender roles, it becomes possible to generate new ways of thinking about gender and being gendered in the world.

GESELL ASSESSMENTS

Gesell Institute of Child Development is a non-profit organization located on the Yale University campus dedicated to promoting the principles of child development for all decisions involving young children. It offers resources for educators and parents to help understand the ages and stages of child development, and how development relates to the individual learning needs of children in the classroom. The institute has two assessments for young children.

Gesell assessments have been used as standardized measures of child growth and development since the introduction of the initial scales in 1925. Long used by pediatricians and revised and updated in 2011, Gesell training and assessment materials focus on direct observation to measure a child's neuromotor, language, cognitive, social-emotional, and adaptive development. The Gesell Early Screener (GES) for ages 3 to 6 years is an instrument that can identify if a child may be at risk for developmental delay. Its more in-depth counterpart, the Gesell Developmental Observation-Revised (GDO-R) for ages 2½ to 9 years, determines a child's overall developmental age relative to chronological age. The GES and GDO-R are complementary assessments designed to be used together in sequence as part of a wider school-based program of screening, assessment, and intervention services. They also can individually be used alone.

The Gesell Early Screener

The Gesell Early Screener 2011 is a screening instrument that assists educators, parents, and other professionals to quickly determine a child's performance level rating (age appropriate, emerging, or concern) in four strands of development: cognitive, language, motor, and social/emotional/adaptive. The GES can be reliably administered by persons with varying levels of experience in 10 to 15 minutes. The GES accurately indicates when further evaluation or observation may be necessary in one or more domains of development. If required, a more in-depth assessment can be achieved with the GDO-R, which measures more deeply cognitive and developmental behaviors through direct observation of the child's responses, processes, organization, overt behavior, and verbalizations on a more diverse set of tasks. If a "concern" is registered in the language, motor, or social/emotional/adaptive strands, a diagnostic assessment in that specialized area is recommended.

The GES consists of eight tasks selected from the GDO-R, a teacher questionnaire, and a parent/guardian questionnaire. The kit includes an examiner's manual, a child recording form that includes a standardized script, a set of manipulatives, teacher and parent/guardian questionnaires, and an auto-calculating version of the GES Strand Scoring Worksheet. It is supported by psychometric data collected from 2008 to 2010 and meets the government mandates for initial screening of a child 3 to 6 years old. The GES requires no specialized training.

Rationale

The rationale for using the GES is twofold: It consists of tasks appropriate for the young child and is based on recent data. Moreover, as a screener, it provides the following essential components:

- A standardized set of tasks that is sensitive to the development of the whole child (social-emotional, physical, cognitive [including language], and adaptive)
- A valid screening measure statistically developed from data collected on a set of GDO tasks

during a national study with a culturally diverse, nationwide sample of children age 3 to 6 years

- Requires no special training and is designed to be administered by persons with varying levels of expertise
- Provides insight into a child's social/emotional/adaptive development, preferences, and behavior at home and in the classroom through parent and teacher questionnaires

Gesell Developmental Observation–Revised

The Gesell Developmental Observation–Revised 2011 is a developmental assessment that should be part of a sound multidimensional assessment system. The assessment assists in understanding characteristics of a child's behavior in relation to typical growth patterns based on sequential, normative stages of development.

The GDO–R is designed for use with children 2½ to 9 years of age, and should be used to inform educators and parents about a child's progress on a developmental continuum. This information is intended to provide insight to guide appropriate instruction and expectations for children based on their developmental stage or level. When combined with other assessments, observations, and reports, the GDO–R contributes to a comprehensive assessment of a child's developmental skills, which is unparalleled in other early education or school placement assessments. The GDO–R can also help determine whether or not a child may need further diagnostic evaluations to decide appropriate planning or remediation in specific areas of development. To maintain the integrity of the assessment, the GDO–R requires participation in a 3-day training workshop. The assessment takes 35 to 45 minutes to administer.

The GDO–R is a performance-based, standardized procedure that measures a child's behavior through direct observation and through surveying parents and teachers. During the child assessment/observation, a sampling of behaviors from various areas of development are observed and then matched with normative patterns of behavior established for each developmental level. In

addition to direct responses to the various tasks, the examiner also considers the child's processes, organization, overt behaviors, and verbalizations in order to determine a child's overall developmental age relative to chronological age.

Description of Tasks by Strand

The primary purpose of the Gesell Developmental Observation–Revised is to observe and evaluate development and academic readiness skills in five areas, or strands:

1. *The Developmental Strand* measures perceptual awareness, visual-motor coordination, short-term visual memory, fine and gross motor skills, and overt behavior. Performance in the Developmental Strand determines a child's developmental age that may be equal to, older than, or younger than the child's actual chronological age.
2. *The Letters/Numbers Strand* measures a child's ability to recognize 26 letters and 12 numbers, to demonstrate one-to-one correspondence, to conserve quantity and perform calculations, and to display short-term auditory memory.
3. *The Language/Comprehension Strand* evaluates a child's attention span, and expressive and receptive language.
4. *The Visual/Spatial Discrimination Strand* measures visual discrimination of written symbols, manipulative shapes, and left and right orientation (for older children).
5. *The Social/Emotional/Adaptive Strand* provides information to evaluate the quality of a child's interactions with peers and adults, emotional regulation behaviors, and self-help skills (using the teacher and parent/guardian questionnaires).

A child's product and process (approach to task) are also evaluated by the GDO–R. Overt behavior is observed for all tasks in the GDO–R, but is scored as part of the Developmental Strand. A child's performance on the tasks for each strand corresponds to the child's performance-level rating for each

strand. Collectively, the performance-level ratings on all strands are used to establish an overall performance-level rating, which corresponds to one of three levels: age appropriate, emerging, or concern.

Description of GDO–R Materials and Kits

The GDO–R Kit includes an examiner’s manual that contains an overview and historical background of the GDO–R, and provides the essential characteristics and behaviors of the ages and stages of development, according to original Gesell theory and other contemporary theories. Complete instructions for administering, recording, scoring, and interpreting results are provided for all tasks. The child recording form is a consumable form (one per child) used by the examiner to record responses to each task as well as verbal and physical behaviors observed during the assessment. The examiner’s script is a spiral-bound booklet that includes the standardized administration script, and the required stimuli cards. The teacher questionnaire collects data about a child’s self-help skills, self-expression, behavioral observations, and classroom preferences. These ratings provide information on three subscales: social behavior, emotional development, and adaptive skills. The parent/guardian questionnaire collects data about a child’s family background and demographics, medical and educational history, home environment, and social, emotional, and adaptive capabilities. The GDO–R kit includes a set of manipulatives.

Rationale

The rationale for using the GDO–R is twofold: It consists of tasks appropriate for the young child and is based on trends determined from recently collected data. Moreover, as an assessment system, it provides the following essential components:

- A standardized assessment sensitive to the development of the whole child (social-emotional, physical, cognitive including language, and adaptive growth)
- A tool for teachers to be keen observers of children, emphasizing developmental levels over chronological age
- Insight into a child’s social-emotional development, preferences, and adaptive behaviors shown at home and in the classroom through parent and teacher questionnaires
- A tool to assist teachers in customizing learning environments so they are developmentally appropriate for all children

The use of the GDO–R system meets both the Individuals with Disabilities Education Act (IDEA) and Head Start mandates. As a standardized tool, the GDO–R can assist in the identification of children who are at risk for developmental, social-emotional, and/or academic disabilities. While not designed to provide a diagnosis of giftedness or specific delays, certain patterns of performance on the GDO–R may indicate that further comprehensive assessment may be necessary in order to gain a deeper level of understanding.

The GDO–R and GES are data-driven instruments designed to help teachers put a child’s developmental profile in a context of learning and lifelong success. When developmental assessments such as the GDO–R and GES are used, it provides a much wider scope of a child’s “next steps” according to normative developmental stages. Perhaps more importantly, it fosters an understanding of observing young learners in multiple contexts that support development (structured play, games, literacy, numeracy, and song). This developmental approach allows individual children to learn at their own pace, rather than follow the prescribed pace of the “pack.” Gesell assessments offer information regarding the whole child, and are invaluable tools in assisting the growth and learning of all young children.

Background

In 1925, pediatrician and psychologist Arnold Gesell first published a set of developmental schedules in *The Mental Growth of the Preschool Child: Developmental Tests for Children 4 Weeks*

Through 5 Years of Age. Still popular today, these schedules are the basis of the 2011 Gesell assessment, known as the GDO–R. The 10,000 participants in Gesell’s work were limited to the children he worked with at the Yale Child Study Center, mainly middle-class Caucasian children from New Haven, Connecticut, and the surrounding area.

During the 1970s and 1980s, school readiness received much public attention. How to serve ready or not-ready children was a predominant topic in the field of education at the time. Pre-first grades, “early fives” programs, prekindergarten, junior kindergarten, and “waiting a year recommendations” were happening virtually everywhere. At one time, 22% of all children were screened using the Gesell assessment to determine readiness for school. During the late 1980s and 1990s, the concept of school readiness became quite controversial. The notion of children being ready or not ready for a school experience was attacked based on the idea that kindergarten teachers should be able to meet the needs of chronologically eligible students, whatever their developmental needs might be. What’s more, some research indicated that waiting a year did not have a significant effect on children’s academic achievement. At the same time, the GDO was justly criticized for lacking the psychometric rigor of other current assessments, and lost favor in many large school districts for this reason.

In order to provide current and scientifically sound normative data to support the validity and reliability of the Gesell assessment, and to appropriately respond to the psychometric standards for technical data demanded by the educational field today, a national study of 1,287 demographically diverse children in 55 schools across 23 U.S. states was conducted. The complete results of the study can be found in the Gesell Developmental Observation–Revised (GDO–R) Technical Report issued in 2012.

GESELL INSTITUTE OF CHILD DEVELOPMENT

Arnold Gesell (1880–1961) was a physician and psychologist who retired from the Yale Medical School faculty in 1949, just before he turned 70 years of age. In addition to teaching, he founded a clinic in 1911 that would later be renamed the Yale Child Study Center. His pioneering research made notable use of the then-new cinematographic technologies to document the developmental stages of over 10,000 children in terms of verbal, motor, social, emotional, and cognitive growth. He was the first to study and document the stages of development and thus is known as the father of child development. He was also the first school psychologist and thus is known as the father of school psychology.

In addition to caring for children and creating an extensive archive that would enable parents, teachers, and others to better understand children’s ages and stages of development, Gesell also trained physicians, nurses, and research scholars who would spend their careers with children in other settings. Two of his former students, Frances Ilg and Louise Bates Ames, seized the occasion of his retirement to open a nursery school and research institute that would continue to explore children’s

development through adolescence. Ilg, a pediatrician with a sizable inheritance, was able to purchase the properties at 310 and 314 Prospect Street, in New Haven, Connecticut, using 310 for research and 314 for the nursery school. They called the combined properties the Gesell Institute of Child Development. Gesell served as a research consultant until his death in 1961.

Ilg and Ames, who wanted to continue their respective areas of research on early childhood through adolescence and to launch the nursery school, found in Janet Learned the perfect teacher to organize and direct the Gesell Nursery School program. Gesell had founded the Guidance Nursery School at the Child Study Center in 1918 and hired Learned as its director in 1938. Learned agreed with Gesell that children were most apt to thrive when parents and teachers communicated well with each other. She left the directorship of Gesell Nursery School when she married law professor Fred Rodell in 1956, but she continued to be supportively involved with the institute and served on the board of directors until her death.

Teachers at the nursery school were mostly hired from women's colleges; some also came from Europe as interns. The Gesell Nursery School started with 2- and 3-year-olds, but soon added 4-year-olds. Every child was given a developmental examination that teachers and parents were expected to watch so they could better shape their curricular and behavioral expectations to match the needs of each child. The Gesell Nursery School soon became a model for other nursery schools and for students in education programs at Southern Connecticut State and Albertus Magnus Colleges. Gradually stories of its success spread through the country, thanks in part to the syndicated newspaper column Ames wrote weekly and in part to the extensive schedule of lectures and consultations Ilg was called on to give. Among the staff members trained by the institute in the 1960s were Judy August, a Gesell Institute board member, and Sally Provence, who was a professor at the Child Study Center.

While the thriving and solvent nursery school served as a training ground for early childhood educators and pediatricians, the other research and treatment programs of the institute were gradually

absorbing the larger portions of availing dollars. Among the early research programs was an investigation of school readiness. With a grant from the Ford Foundation, Gesell was able to show that a large number of the children failing in elementary school had not been ready to start school when they did; in other words, chronological age does not necessarily coincide with developmental age. More attention needed to be paid to the developmental differences of an individual child or the wide disparity in school readiness between a 5-year-old born right after the school entry cutoff date (the oldest child in a class) and one born in the two or three months preceding the cutoff date (the youngest of the class) of the same year. This research would have a wide impact, and became the incentive for development and publication of many similar developmental assessments, some of which turned on their "parent," so to speak, and built reputations as competing versions. However, many teachers and administrators continued to rely on the original Gesell Developmental Observation (GDO) assessment as the one that best served their children and the only assessment to provide a developmental age for the child.

The institute during the 1950s, 1960s, and 1970s was thriving and was sought out for its research in vision and speech development, and influence on the formation of personality. Many vision school fellows did postdoctoral work at the institute. Multiple clinical services were available for the public, for vision and speech, and psychological counseling through adolescence. The Medical Department was added in 1972. Because the institute was now working with individuals beyond adolescence, its name was changed in 1982 to the Gesell Institute for Human Development.

Despite its successes, the nursery school was unable to sustain itself and closed at the end of its 29th year, in June 1980. Ilg died the following year; she was 81. Ames continued well into the 1990s to teach, to work with the institute's National Lecture Staff (NLS), and to update and publish the institute's year-by-year guides to child development (*Your One-Year-Old*, *Your Two-Year-Old*, on up to 14), which parents today still find as relevant as they did when they were first issued in

the 1940s under different titles. Ames died in 1996 at age 88.

One of Ilg's most important legacies was the formation of the NLS in 1970. This network grew out of Ilg's work with Gesell-trained educators across the country. Women and men who subscribed to Gesell's approach to child development carried on workshops for teachers, parents, and others to introduce them to the Gesell Developmental Observation and show them how to use it properly. To assist her in developing curriculum guidelines, Ilg hired Jackie Haines in 1969 and Norman Heimgartner in 1970, both from Colorado. Heimgartner conducted countless workshops as a member of the NLS and continued to teach the Gesell philosophy at universities in the West, and also in Thailand and China. Today the NLS is still doing the work much as Ilg had envisioned and has 10 staff members conducting about 40 workshops a year in multiple states, with satellite programs in Germany and China.

When the Medical Department and clinic closed in 1989 due to financial hardships, Gesell Institute sold its two buildings to Yale University and used a part of the proceeds to establish the Arnold Gesell Professor of Child Psychiatry, Pediatrics, and Psychology. Linda Mayes was first honored with that appointment and still maintains the position today. She also serves on the institute's Advisory Council. In 1990, Haines became director of the institute. During the 1990s and early 2000s, Haines and Annette Watert, who was hired as the administrative assistant in 1982, were the only staff left (after the death of Ames in 1996). They were able to keep the institute and the NLS alive through the 1990s and into the 21st century due to GDO customers who continued to buy the assessment and schedule workshops across the country.

After some tumultuous times during the 1990s, the board became stronger and reorganized in the years after 2000. The board hired an outsider with a business background, Elyse Waterhouse, to lead the organization in November 2002. She stayed not quite 5 years but was able to accomplish the development of strong business policies, job descriptions, and procedures. Haines retired in 2003.

In November 2007, after a national search, the board hired Marcy Guddemi, a nationally known

child development advocate and expert with considerable experience in educational assessment publishing and a master's degree in business administration, to lead the institute. She immediately embraced the job and set in motion the following:

Updating Assessments. The institute completed a much-needed national re-norming study for the GDO with the psychometric supervision of McREL (Mid-continent Research for Education and Learning). This resulted in the publication of Gesell Developmental Observation-Revised (GDO-R) and the new Gesell Early Screener (GES), both in 2011.

New Professional Image. The institute developed new marketing tools and publications, a new website along with a presence on social media, a presence at the annual National Association for the Education of Young Children (NAEYC) convention with a commercial display, television appearances, a DVD called *Ready for Kindergarten*, and the publication of three new booklets, *Ready or Not for Kindergarten*, *Gesell's Guide for Parents and Teachers: Understand the Relationship Between Families and Schools*, and *Pretend Play and Brain Growth: The Link to Learning and Academic Success*.

A National Conference Marking Gesell Institute's 60th Anniversary. Over 300 people gathered October 10, 2010, at the Omni on the Yale University campus to participate in the Early Childhood LEADership Conference. Featured speaker of the LEAD (Lead, Educate, Advocate, and Do) conference was pediatrician T. Berry Brazelton. The conference proceedings can be found on a free DVD titled *Community Early Childhood LEADership E-Kit*, published in 2012 and available online. The e-kit also includes a 30-minute video on the "Crisis in Early Childhood Education" and a tool kit for conducting community conversations. This e-kit was distributed to every member of the National Association of Elementary School Principals in September 2013 along with their journal, *Principal*.

Name Change. The name of the organization was restored in 2011 to the Gesell Institute of Child

Development, reflecting the return to its original focus on child development.

National Marketing Study. In 2013, under the leadership of board president Barbara Stern, the institute hired Words and Numbers, Inc. to conduct a national marketing study of the organization. Its conclusions resulted in the hiring of a national sales director and a detailed marketing plan.

Positioning the Institute as a Major Player in Advocacy for Young Children. Through numerous speeches nationwide; articles in professional journals, trade publications, magazines, and newsletters; expert advice for journalists seeking information; and involvement in the New Haven Early Childhood Council, Gesell Institute has established itself as a thought leader locally, statewide, and nationally.

Today the institute is both (1) an advocate for young children and (2) a resource for teachers and parents nationwide and internationally in some markets. The institute's mission, as stated on its website, is "to promote the principles of child development for all decision making for young children," with an emphasis on learning through play and the rights of the child as guaranteed by the 1989 United Nations Convention on the Rights of the Child. Meanwhile, the Gesell Institute continues in the same building at 310 Prospect Street, renting its office spaces from Yale and sharing the building with Yale's Edward Zigler Center in Child Development and Social Policy, School of the 21st Century, and the Connecticut Academy of Arts and Sciences.

As Gesell Institute of Child Development celebrated its 65th anniversary in 2015, the institute is poised to launch the next decade of leadership with its Leaders Forum on Economic Development and Early Childhood and subsequent Year of Advocacy. This all based on the pioneering work of its namesake, Arnold Gesell, who once said, "The measure of a society is its reverence for children." The Gesell Institute is one such measure.

GIFTED EDUCATION

Young intellectually gifted children are defined as those who have the ability to perform at a level significantly beyond their age cohort. They have a range of characteristics, both cognitive and socio-affective, that set them apart from their chronological age-peers and require modifications in educational contexts.

Cathie Harrison (2003) defined a gifted child as

one who performs or has the potential to perform at a level significantly beyond his or her age peers and whose unique abilities and characteristics require special provisions and social and emotional support from the family, community and educational context. (p. 8)

This definition serves to highlight the special needs that young gifted children have in terms of their social and emotional development and support, as well as special provisions to meet their intellectual needs. In an early childhood setting the interplay and relationships among family, educational context, and community are paramount to healthy development.

Appropriate educational provision for young gifted children is important for a range of reasons. First, all children, regardless of level of ability, are entitled to a stimulating and challenging early childhood education. Second, young gifted children who are not challenged risk experiencing boredom that can lead to underachievement and disengagement with future educational experiences.

Furthermore, young gifted children are a valuable natural resource. As such, there should be an emphasis on nurturing their abilities for the future benefit of society.

Conceptions of Giftedness in Early Childhood

The field of gifted education has its roots in the early 1900s in the work on intelligence by Alfred Binet and Theodore Simon, Lewis Terman, and Charles Spearman. Spearman's concept of general intelligence, or *g*, and issues related to how *g* could be measured in young children meant that there was a perception that giftedness in early childhood could not be validly predicted or measured. Therefore, there was little research conducted in the area. Until the early 1980s, the study of giftedness in early childhood largely relied on retrospective studies, in which the childhood traits of eminent people were analyzed and the characteristics of gifted children in early childhood extrapolated from that evidence.

As concepts of giftedness broadened to include domain-specific aptitudes, such as the work of Howard Gardner on multiple intelligences and J. P. Guilford on the structure of the intellect, it became apparent that young gifted children could be more reliably identified as there were clear indicators of the presence of domain-specific abilities, such as early or self-taught reading. This opened the way for research into the identification of younger gifted children.

Characteristics of Young Gifted Children

Following are the cognitive and socio-affective traits most commonly seen in young gifted children. It is important to note that not all children will display all these traits and that educators should be looking for a cluster of traits when identifying young gifted children.

Cognitive Characteristics

Young gifted children are known for their atypical developmental patterns. That is, they tend to reach developmental milestones earlier than

children of average ability. Where a typically developing child might utter his first word at 12 months, a gifted child may speak at 9 months. Some researchers have characterized giftedness as *asynchronous* or *out-of-step* development. A young gifted child may be chronologically 5 years, but have the reasoning capacity of a 7-year-old and the fine motor skills of a 4-year-old.

Some of the cognitive traits that have been observed in young gifted children include rapid rate of learning; excellent memory and recall; intense curiosity; advanced language, including an early interest in word games and word play; a large and well-developed vocabulary at an early age; highly developed reasoning ability; driving desire to "find out"; and highly observant.

Early and self-taught reading is often associated with giftedness. However, many gifted children do not commence reading until formal instruction at school, so while many early readers may be gifted, not all non-readers are not gifted.

Socio-Affective Characteristics

Just as young gifted children's cognitive development is atypical, so too their socio-affective development may also be advanced. Traits associated with giftedness in young children include a preference for older playmates; early interest in moral issues and abstract concepts such as love, death, and freedom; interest in one particular topic (e.g., dinosaurs, airplanes, road maps) to the point of bordering on obsession; intense sensitivity; and empathy.

It is important to note that most young gifted children have good social skills and are popular with their peers. However, some young gifted children may encounter problems in the early childhood context when their interests and abilities are substantially different to those of their peers. For example, a 3-year-old with an interest in chess may be perceived as "weird" by other children. In turn the 3-year-old may feel frustrated in the early childhood setting if there are no other children with whom she can share her interest. A preference for solitary play, when there are no like-minded children in the early childhood setting, may be misinterpreted by early childhood educators as immaturity.

Identification of Young Gifted Children

Young gifted children can be identified in a variety of ways. Researchers in the field of gifted education have consistently reported that “multiple criteria” identification, where a variety of different sources of information—both subjective and objective measures—are used, is best practice. Objective measures may include traditional tests, such as IQ assessments and other standardized measures of ability and achievement. Subjective information, perhaps more helpful in the early years, includes checklists and anecdotal information from parents and caregivers, early childhood teachers, and medical practitioners (who may have noted early or advanced development). Research has consistently demonstrated that parents are an excellent source of information about their children and better at identifying young gifted children than teachers who have not had training in the field. For this reason information provided by parents and accounts of home behavior should be taken into account when identifying gifted children.

Provisions for Gifted Children in Early Childhood Education

Surveys of early childhood provision in the United States have revealed a lack of programs for gifted children in preschool and kindergarten. Most of the literature relating to giftedness in early childhood has focused on the identification of young gifted children. There has been some descriptive information about types of programs used with gifted preschoolers but little quantitative information or program evaluation.

Paradoxically, despite the lack of provisions for young gifted children, the out-of-home early childhood environment has the potential to be one of the most responsive educational contexts for these children. Researchers have suggested three reasons why this may be so. First, there is a narrower span of mental ages and abilities than would be found in regular school classrooms of older children; second, the child-focused and naturalistic nature of early childhood education is better equipped to

catering for individualized programming, since, unlike in school, there is rarely a set curriculum that has to be followed; and third, early childhood teachers typically use naturalistic and authentic observation of children’s interests and abilities.

Teachers with training in gifted education are known to be more effective teachers of the gifted than those who are untrained and are better able to foster higher-level thinking skills and promote creative thinking. However, there is very little training in gifted education provided for early childhood teachers at the tertiary level. This appears to be a serious omission given the critical importance of the early childhood years for later development.

It is important that a developmentally appropriate response to the needs of young gifted children should not merely be an early introduction to formal schooling. The challenge for early childhood educators lies in finding ways to cater to the advanced interests of young gifted children using play-based and emergent curriculum.

The level of the provision depends, in part, on the level of giftedness of the child. Just as children with more severe disabilities require more extensive educational accommodations than children with mild disabilities, so too exceptionally and profoundly gifted children require different modifications to their educational experiences than children who are mildly gifted.

In the case of exceptionally and profoundly gifted children, usually those identified by a psychologist as having an IQ in excess of 160, early entry to school and subsequent full-year acceleration may be the most suitable educational interventions. The educational needs of mildly gifted children (IQ 115–129) may well be able to be met within the regular early childhood classroom, provided that the educator has an understanding of the traits of young gifted children and a willingness to provide a curriculum that follows the child’s interests.

GRADE RETENTION

Grade retention refers to repeating the same grade level in consecutive years. The decision to retain a student is most frequently made when a child experiences difficulty with academic subjects and fails to reach performance standards or appears to be socially immature for his or her age or grade level. Factors that are often associated with an increased risk of retention include living in poverty, frequent changes in school or chronic absenteeism, reading and behavior problems, and difficulties with peer relationships. This entry provides a brief overview of the origins of grade retention, discusses research that informs our understanding of the negative outcomes associated with grade retention, and identifies some effective alternatives to grade retention.

Origins of Grade Retention in the United States

Grade retention was put into place in the U.S. educational system in the mid-19th century as part of the shift toward a system of mass education and the expansion of compulsory education laws. From the 1830s to the 1860s, the percentage of school-age children attending school nearly doubled. In response, schools shifted from multi-age, one-room schoolhouses to a uniform, graded system of education in which cohorts of same-age students were instructed in a prescribed grade-level curriculum. Students' mastery of grade-level content was assessed to determine individual academic achievement and prevent students with academic challenges from advancing to the next

grade. Current research does not support the practice though it continues to be commonplace in the United States, despite the availability of alternative strategies for supporting struggling students.

Outcomes Associated With Grade Retention

Given the widespread practice of grade retention in the United States (estimates exceed 3 million children retained annually), it is notable that collective empirical evidence reveals deleterious effects of grade retention on both academic and social-emotional outcomes. During the past four decades, there have been five seminal reviews that have examined the effects of grade retention on student achievement. Throughout these reviews, academic achievement was generally measured using achievement test scores, grades, or standardized norm-referenced achievement tests. One of the first systematic reviews examining the efficacy of grade retention on student learning was conducted by Gregg Jackson in 1975 and included 30 studies published between 1911 and 1973. The purpose of the review was to determine whether students with academic or socioemotional difficulties generally benefited from grade retention. Jackson concluded that there was no evidence to support the use of grade retention over promotion.

Two meta-analyses conducted by Thomas C. Holmes and colleagues in 1984 and 1989 examined studies published on grade retention and included comparison samples matched on various dimensions such as intelligence, achievement tests, and socioeconomic status (SES). The results of each of these meta-analyses revealed that there were negative effects associated with grade retention, including lower academic achievement, higher socioemotional maladjustment, and lower self-concept. Similar results were found by two more recent meta-analyses, by Shane R. Jimerson in 2001 and Chiharu S. Allen and colleagues in 2009.

Grade retention in kindergarten through third grade has also been linked to negative long-term consequences. Whether students are retained due to academic difficulties or developmental delays, research findings consistently demonstrate that

retention neither benefits students' academic achievement nor enables struggling students to catch up with their peers. Moreover, research has shown that adolescents who were retained during their early childhood years are more prone to emotional distress, low self-esteem, suicidal thoughts, poor peer relations, use and abuse of controlled substances, early onset of sexual activity, and violent behaviors. Retention is also one of the most powerful predictors of dropping out of high school.

Commonly referred to as "academic redshirting," late enrollment in kindergarten is an increasingly popular practice among parents and educators. Another strategy has been "transitional kindergarten" or "transitional first grade," which requires an additional year in either kindergarten or first grade. Since these options do not typically involve any specific targeting of individual needs and often have class sizes equal to any other grade, none have been found to be effective in enhancing academic or adjustment outcomes.

The research indicates that retention does not lead to improvement of educational success and that it is ineffective for addressing academic or social-emotional intricacies. Although students may initially demonstrate academic improvement when retained, numerous studies reveal a decline in gains within two to three years' time. Research has yet to identify particular students who will likely benefit from grade retention, and the research reveals that most students endure negative academic and emotional outcomes.

Based on existing research, grade retention is contraindicated, as it is not supported as an evidence-based intervention and is associated with numerous deleterious outcomes. Numerous studies reveal negative effects of grade retention, including lower academic achievement, higher socioemotional maladjustment, and increased risk for school withdrawal.

Effective Strategies

The confluence of research demonstrates that neither retention nor promotion adequately addresses the needs of students with academic or behavior challenges. Rather, education professionals are

advised to utilize research-based strategies to promote learning and school success by improving children's cognitive and social skills. To effectively benefit children with low achievement or challenging behaviors, a combined approach of promotion plus research-based interventions will likely yield the most positive results.

Although no single intervention will address every child's academic needs, evidence-based practices incorporated throughout their education are likely to facilitate children's academic success. Recommended practices include parental involvement through regular contact with teachers and homework supervision, early reading and developmental programs to support children's academic success and enhance language and social skills, school-based mental health programs to support children in their social and emotional adjustment, tutoring and mentoring programs, summer school, tutoring, and other interventions that target specific academic skills. It is also important to carefully attend to the transition of students from preschool to kindergarten and from kindergarten to elementary school, as evidence shows that children are more successful when they experience continuity. Evidence-based practices should include a focus on remediation for struggling students and also on prevention by supporting all students. Collaboration between all educational professionals and families is key for facilitating student success.

A "promotion plus" model in which students promote to the next grade and receive targeted interventions to address individual needs is recommended as best practice. Key elements include parent-teacher collaboration, high-quality assessment and progress monitoring, and targeted early intervention to address academic and socioemotional difficulties. Implementing these educational practices will foster academic progress and socioemotional development.

GRANDPARENT ROLES

Use of the term *grandparent roles* provides a means to define how grandparents might interact with their grandchild. Sometimes it is referred to as styles of grandparenting. There are a number of possible roles for grandparents to fill as they develop a relationship with their grandchild. This means opportunities for grandparents to be creative in finding what works best for them and their grandchild.

This entry addresses an important aspect of early childhood education. Much has been written about the value of intergenerational or skipped-generation interactions. This entry provides a more complete view of family life for both young children and their family.

Overview

There are many similarities in what the roles of a grandparent might be. At the same time, there are also differences. Each grandparent is somewhat unique based on individual interests, talents, and life experiences. So it makes sense that the role of a grandparent includes a variety of possibilities. In other words, the grandparent experience is not identical for each person.

Some differences may come from the configuration of the family. Divorce, remarriage, adoption, or the distance that grandparents live from their grandchildren can make it difficult to build a face-to-face relationship. Technology provides grandparents additional ways to interact with their grandchildren.

Whatever role a grandparent selects can work. Part of the magic is the relationship that develops between grandparent and grandchild. Each seems to bask in the presence of the other. Part of what works so well may be the unconditional love that is shared by both.

Roles of Grandparents

Although grandparents may express similar feelings about their experience as a grandparent, there are differences. Each person brings their own unique self to the experience. Some factors that influence grandparent styles are culture, ethnicity, gender, race, family traditions, family structure, and the experience the grandparent had when they were a grandchild.

Sometimes grandparents-to-be are not at all excited as they anticipate this new relationship. They may view it as a sign they are getting older or think they do not have time for grandchildren. Becoming a grandparent does not mean that the person is old. There is comfort in knowing the decision about the grandparent role is up to the individual. How to be a grandparent is whatever that person chooses.

Just as having a relationship with both parents is important to a child, having a relationship with grandparents is important in the life of the child. Grandchildren are equally important to their grandparents. This is true of grandparents, step-grandparents, adoptive grandparents, or grandparents

who find themselves in the role of raising their grandchild. The unconditional love each has for the other can make the grandparent–grandchild relationship a special one for both sides.

Ongoing research by Arthur Kornhaber and Kenneth L. Woodward identifies grandparent roles such as family historian, living ancestor, nurturer, mentor, role model, crony, wizard, and hero. Usually grandparents experience more than one of these roles. Let's explore how this might look.

Family historian and living ancestor roles help the past come alive. Whether or not the grandparent is interested in genealogy, grandparents bring memories of the family members they have known. They can share the family history they experienced, as well as history learned from family about ancestors never met. Grandparents may share how family members are related to each other and talk about events that were important to the family. Some grandparents are natural storytellers, sharing memories of past family traditions to be passed on to the next generation. All of this can help children decide how they fit in as part of the family. Remembering the good times and the bad helps family keep life in perspective.

Nurturer, mentor, and role model roles provide grandparents with opportunities to share the characteristics, morals, and values they consider to be important. Caring and positive attitudes allow grandparents to set an example as they encourage the grandchild even in challenging situations. Grandparents may be the caregiver on a temporary or full-time basis. As nurturer, the grandparent may provide food, babysit, drive the child to events, or be a person the child can confide in. They can also be supportive of the child in a variety of situations, thereby demonstrating unconditional love by finding ways to encourage rather than control the child. As mentor, the grandparent teaches skills, knowledge, and attitudes to their grandchild. As a role model, the grandparent sets an example of what is important to them including ethics, religion, and how to handle situations when things do not go as planned. The grandparent can help the grandchild know how to persevere and carry on when a crisis occurs.

Crony, wizard, and hero roles involve the sensitive and creative sides of a grandparent. To be a crony is to play, talk, and share time as an equal with the grandchild. The role of wizard uses imagination and feats that seem possible only through magic. Grandparents have the opportunity to surprise and amaze. A hero role involves trust and respect. It may save the day for the grandchild in the future if the child is comfortable sharing innermost thoughts with a grandparent.

It can be hard to put into words the experience of being a grandparent. Grandchildren make it possible to be exhausted and energized all at the same time. Grandparents are important in the life of their grandchild. But grandchildren are also important in the life of their grandparent.

GRIEF AND LOSS, YOUNG CHILDREN'S UNDERSTANDING OF

Young children are exposed to death and loss, even if adults and the culture at large do not acknowledge or recognize it. They experience the deaths of children, family members, other significant adults, neighbors, pets, bugs, plants, and wild animals, as well as death-related portrayals in the media. Losses can include a family move or a friend who moves away, parental divorce or loss of a parent's dating partner, end of a friendship, or loss of prior preschool environment and teachers when they move on in school. Understanding children's thought processes related to death and loss provides insights for adults into how a child responds to a loss and how to provide appropriate support, including helping the child clarify and manage loss-related experiences. This entry provides information on children's understanding of death and the cognitive, cultural, and experiential elements that influence it, as well as the role that adults play in children's growth in understanding of death and loss.

Overview

Children make active efforts to understand death. It is normal for them to have thoughts, feelings, and curiosity about death. Children's understanding of death and grief is related to their developmental level, current and previous experience with death or other losses, personality, patterns of communication, support or comfort, and societal forces. The attitudes they develop toward death are derived from many sources.

Children do not necessarily think of death in the same ways as adults, but they do develop concepts of death as they try to make sense of their experiences. Young children do not have to grasp finality of death or the cessation of bodily function in order to react to separateness from the deceased. Even young infants recognize loss, as reflected in their display of separation anxiety.

Cognition and Understanding of Death

Young children's understanding of death involves development, over time, of four general components: finality (that death cannot be reversed by magic, food, water or medicine), inevitability (that all living things die, including oneself), cessation of bodily functions (that, unlike sleep, death ends all feeling, movement, thought, and abilities), and causality (understanding that death can be the result of internal or external causes). Children's understanding of death and loss reflects their stage of cognitive development. Toddlers and young preschoolers are egocentric and focus on the here and now. They view death in concrete literal terms, believe death is temporary and reversible, and do not understand that a dead person is nonfunctional. Older preschool-age children engage in magical thinking (that they may have contributed to the death or could bring the person back) and they begin to understand that death is irreversible and universal.

Children move through these stages at somewhat different times and are influenced by their experiences. They also have periods of transition during which they may display characteristics common to the cognitive stage they are exiting, as well as the one they are entering. Children under stress may also regress to an earlier stage of cognitive development. They may also confuse adults by being sad one minute and playing happily the next, a normal reflection of how children deal with crisis.

Because of their cognitive developmental stage, a child's remembrance of events and situations may seem distorted and fragmented to adults. This situation is further complicated by the euphemisms we use to discuss death. The child with concrete cognitive processing who is told, "Grandma is on vacation," may display a strong reaction six months later when the parents plan a vacation. "Going to see Grandpa's body" may imply that he has lost his head.

Revisiting Grief

Some manifestations of grief and questions about loss may not appear until a couple of years later.

In addition, children who experience a significant loss will often revisit the death at later times when they have new developmental and cognitive capacities that enable them to add to what they previously understood in order to create a revised, fuller meaning of the loss. The phenomenon of regrief occurs when children process the experience from a different position than was possible when they were at an earlier stage of development. It can include new questions about the loss, new definitions of death, a different expression of grief, and revised strategies for dealing with the loss.

Experience, Environment, and Culture

Children living in diverse cultural and socioeconomic communities experience death to different extents and in different ways, with varying exposure to violence, starvation, war, multiple losses, television or Internet graphic violence, and direct witness to death.

Through participation in their culture, children learn to think and develop skills for problem solving. Some of the problems they actively seek to solve relate to understanding death, loss, and their related hardships. Some societies or cultures send messages to children that death is not a topic that should be discussed or that death-related events are only for adults. Other societies do not send these messages.

Adults' Roles and Child Understanding of Grief

Based on the messages they received in their culture, adults may disregard a child's grief because they have the preconceived notion that children do not grieve and they believe children are too young to understand. Through this lens adults fail to recognize the signs of a child's grief. Intense sadness, anger, depression, or fearfulness are common feelings of children dealing with grief and loss. The way feelings are manifested depends on the age, cognitive development, culture, and experience of each child. Grieving young children commonly display exaggerated fears; fear and disruption in attachment relationships; repetitive

traumatic play, where themes from the traumatic situation repeatedly appear in their play; and persistent regression.

However, children experience their own grief as well as the grief of those around them, even when adults try to hide their grief. Children's fears can be heightened when adult reactions are unclear or unusual as compared to that adult's normal behavior. Thus, adults' attempts to be strong and hide their grief from children add further confusion. In contrast, adults who model a grieving process, display feelings, and acknowledge that relationships are important aid children in their understanding of loss. Without this, children can be confused as to the value of relationships.

Children benefit from naturally occurring opportunities to learn about death and loss. Attempts to help them avoid experiencing pain, such as exclusion from discussions of death and mourning-related ceremonies (i.e., funerals), or replacing a lost object quickly (e.g., a replacement animal following the death of a family pet, or a new toy to take the place of something lost) deprives them of learning experiences.

GUIDANCE WITH GIRLS

Guidance with girls uses developmentally appropriate guidance strategies to help all children, especially girls, develop necessary skills to experience and advocate for environments free from gender bias. Guidance is a widely accepted approach to teaching children the skills and behaviors needed to be successful within a particular environment. Guidance with girls requires adults to examine their current beliefs and guidance practices, and adjust to include gender equality as a goal. This entry examines adjustments to general guidance strategies to provide guidance with girls.

There is broad agreement about developmentally appropriate guidance strategies within early childhood education. Multiple resources identify similar strategies and approaches for guiding young children. Specifically, Dan Gartrell has thorough texts on guidance in early childhood. Most resources do not specifically address guidance with girls. Guidance with girls happens in many ways and in many places—in interactions with girls, with boys, with other adults, and with families. Guidance with girls differs from regular guidance in the ways discussed in the following sections.

Examine Current Beliefs and Practices

Adults need to examine current beliefs and guidance practices to determine ways they may inadvertently contribute to children learning gender biases. Like young children, we receive many messages from family, friends, and media about what it means to be a boy or girl, a man or woman. A core value of early childhood education is equality. The field is predominantly made up of women. Yet the number of women who believe in feminism—defined as equality between the sexes—is low. Because child development theory indicates that understandings of gender identity and gender roles become stable during the preschool years, it is critical that teachers of young children ensure the messages they send promote gender equality. Guidance contributes to what children learn

about gender; therefore, reflecting on guidance practices is the first step toward guidance with girls.

Guidance with girls requires adults to know the gender expectations and models provided for children within home and community. Children may be learning gender models that do not promote gender equality. Conflicting ideas about gender present opportunities to explore issues with children. Having developmentally appropriate conversations with children about gender roles will help adults recognize nascent gender stereotypes that might lead children to exclude themselves or others from important learning opportunities. Conversations with families can explore practices and beliefs that promote or inhibit gender equality.

Specifics to Teach Girls

There are specific things that girls should be taught in order to fully developing their potential. First, girls should be taught that they are strong and capable beings. Many media sources portray women and girls as helpless victims who need saving. This view undermines the development of a positive sense of self. Girls should be taught that what they need, want, say, think, and feel matters. Traditional gender biases teach girls that their needs and wants are less important than the needs and wants of others. When girls offer ideas or suggestions, traditionally they might be discounted or ignored. Myra Sadker and David Sadker's research confirmed that teachers in classrooms tend to respond to boys more quickly and more often than to girls. Adults must listen and respond to girls and be supportive and fair in their interactions. Girls must also be taught how to be assertive *and* caring. The traditional gender scripts teach girls to be nurturing and caring by placing others' needs before their own. Caring is a strength, but we also need to teach girls how to be assertive. Finally, girls need to know how to recognize, respond to, and recover from interactions that discount them based on their gender. We can teach these by adjusting guidance strategies to focus intentionally on guidance with girls.

Have Clear and Consistent Expectations for Children

Making sure a child knows what is expected behavior and consistently addressing behaviors not meeting expectations is a foundational part of guidance. In guidance with girls, expectations for gender equality and inclusion must be consistently promoted. Expecting children not to exclude others from play because of gender is important. If children are excluding other children based on a gender bias, adults must clarify the expectation of gender inclusion and provide opportunities for children to become comfortable playing with mixed-gender groups and with trying new experiences. This will present opportunities for children to examine emerging beliefs about gender and for teachers to help children rethink biased assumptions. If a child is using hurtful gender-related words, adults must intervene to teach prosocial ways of communicating.

Be Firm but Friendly

Being firm but friendly when supporting children in learning behavior expectations is important. Respecting children as they navigate between what is acceptable and not acceptable within a particular environment is critical in making the children feel safe and trust the adults. Guidance with girls requires adults to help children recognize when their actions violate the expectation of gender equality. However, this needs to be done in a nonjudgmental and supportive way. When the expectation for gender equality has been clearly communicated, being firm but friendly when addressing exclusion or unkind actions based on gender is important.

Supportive Environments

Making sure that the environment is designed to support children's success is another feature of most guidance programs. Guidance for girls calls extensively on anti-bias education in examining the early childhood environment. Avoid play materials that are unnecessarily gendered—such

as sparkly art supplies or camouflaged tools. Make sure that posters, pictures, and books reflect girls and boys doing a variety of nonstereotypical activities. Make sure that all children have opportunities to participate in each of the classroom chores. Carefully select gender-neutral language when teaching children. Help children recognize when materials or language within the environment is gender biased.

Teach Problem-Solving Skills and Advocacy

Teaching children to advocate for themselves or others while solving problems is important. Once children recognize that no one should be excluded from activities because of gender, this exclusion presents problems for children to solve. Having teachers support children in learning how to address gender exclusion and respond to gender slights is essential in guidance with girls.

GUIDED PLAY

When thinking about a child's day, it is common to classify time as playtime (e.g., recess, free play on the playroom floor) or instructional time (e.g., direct instruction in class, worksheets for homework). Indeed, many schools are decreasing recess in favor of direct instruction. However, recent research suggests that a "sweet spot" for learning exists between these two extremes. Guided play, in which a more experienced play partner follows a child's lead, but scaffolds the child's learning via exploration, has garnered much support. This entry reviews this evidence, discusses the benefits of this method, and offers suggestions on how to incorporate guided play in early childhood education settings.

Think about a child learning about shapes. One vision calls to mind a room of students sitting quietly and using worksheets. Another envisions a class playing with a box of shapes but without teacher support. Between these two extremes lies a third alternative.

One can imagine a teacher sitting with students and presenting them with a variety of triangles and other shapes—some isosceles triangles, some fat triangles, some triangles with one acute angle that renders them thin, and some non-triangles with partially open sides. After children play, one child holds up an equilateral triangle and says, "This is a triangle!" The teacher then picks up a skinny triangle and asks the group, "Is this a triangle?" Some children say yes and others aren't sure. The teacher then asks, "Why do you think this is a triangle?" The teacher—qua coach—works with children's responses to encourage them to understand and articulate what all triangles have in common: three closed sides and three corners.

While it may seem more efficient to *tell* children what a triangle is, children given the opportunity to explore and discover this for themselves will know more about triangles than those who were simply told. Kelly Fisher and colleagues found that children who learned via *guided* play, in which the teacher scaffolded their understanding, showed

better learning compared to children just told and to children encouraged to play with shapes on their own. This was especially true for when it came to transferring their shape knowledge to new instances.

The benefits of guided play exist beyond spatial cognition. Researchers such as Geetha Ramani and Robert Siegler found that playing linear math board games has long-lasting benefits for low-income students. Others note benefits of guided play for language learning and literacy. Indeed, support for this kind of playful learning has appeared across hundreds of studies. Louis Alfieri and colleagues completed a meta-analysis comparing unassisted discovery (free play), explicit instruction, and enhanced discovery (guided play). Guided play resulted in the best learning in most circumstances. When adults have a learning goal in mind, guided play is optimal. Guided play requires active, “minds-on” learning, breeds engagement, makes the material meaningful by encouraging the child to link it to previous knowledge, and often involves high-quality social interaction with an adult. Guided play engages children at their “sweet spot,” inviting them to participate and actually think.

Why might guided play offer an effective pedagogy? At first glance, it would appear that direct instruction should promote the best learning. In these contexts, we tell children exactly what we want them to learn. There is no ambiguity. However, a recent proposal by Deena Weisberg and colleagues suggests that guided play may work because it allows children to adopt a positive mindset toward schooling, encouraging them to be agents in their own learning while adults scaffold them toward a curricular goal. Called *mis en place*, this element sets the stage, supporting engagement and questioning. Indeed, Elizabeth Bonawitz and colleagues discuss the “double-edged sword” of pedagogy. When we tell children what we want them to know, it appears that they assume that this instructed information is *all* there is to know; they are no longer willing to engage in exploratory play. They will do what we want them to do without further engagement with the task.

How might one use guided play in early childhood education? The teachers’ role is crucial. They must prepare the lesson with a learning goal in mind, but must allow the child to direct the experience. A teacher attempting to teach a lesson about multiplication and division may put circles (chocolate chips) on the table and tell children to pretend they are bakers creating cookies. If children follow this narrative and explore how to distribute the chocolate chips among the cookies, they may stay active and minds-on while avoiding distraction. Without the teacher, these are just circles on a table; but with the adult supporting this play with a learning goal, this high-quality social interaction quickly becomes a meaningful mathematics lesson, putting children in the most receptive mindset for learning. There need not be tension between free play and didactic instruction. Guided play highlights what is to be learned through inviting children’s participation and maximizing learning.

GUIDING BEHAVIOR

In the terms of developmentally appropriate practice, guiding behavior is synonymous with teaching for healthy emotional and social development. The term often used for teaching that guides young children's behavior while empowering healthy emotional and social development is *guidance*. In their landmark 2009 work for the National Association for the Education of Young Children, Carol Copple and Susan Bredekamp establish that good guidance includes both individual and social dimensions.

Individual Dimension

Psycho-neurologists who study brain development increasingly focus on the importance of managing stress as a dynamic in healthy emotional and social development. Due to neurological issues, environmental issues, and often both, some children experience unmanageably high stress levels. Jack Shonkoff and Andrew Garner make the case that this *toxic stress* hyperstimulates the amygdala, the center of the brain that senses threat and triggers stress hormone reactions and related behaviors.

An immediate impact of toxic stress is that the child is quick to show survival (“fight, freeze, or flight”) behaviors, which often include aggression, in relatively normal everyday situations. The child feels threatened and acts out in a mistaken effort to protect physical and psychological well-being. In fact, toxic stress can result in posttraumatic stress-like reactions by the child, often mistaken by adults as willful challenging behavior—the child intentionally choosing to be “bad.”

Megan Gunnar, Adriana Herrera, and Camelia Hostinar report that the long-term effect of toxic

stress on emotional and social development of the child can be devastating. The young child can become vulnerable to a cycle of toxic stress, leading to an aggressive survival reaction that results in punitive adult reaction and peer rejection, which in turn leads to debasement of self-identity and continued toxic stress.

A central goal of guidance is to provide leadership that assists the child to build *resilience*. Ann Masten defines resilience as the ability to use emotional and social skills to overcome, or bounce back from, the effects of difficult conditions and stress in one's life. Karen Cairone and Mary Mackrain write that key in this effort is the creation of external and internal protective factors.

External protective factors are improved conditions in the environment at home and at school that reduce sources of stress in the child's life and restore the child's ability to build trusting relationships with significant others.

Internal psychological factors are attributes and skills that empower the child to manage stress, express strong emotions in non-hurting ways, and build healthy relationships—in other words, to begin a path of healthy emotional and social development.

Directly with individual children, early childhood professionals build a positive relationship (secure attachment) with the child, so that the child's sense of trust grows and a willingness to learn new skills is reinforced. Sustained warm personal contact with the child, both during and outside of conflict situations, is essential. Through this relationship the caring adult guides the child to make gains in initiative capacities, sociability, a sense of humor, perspective-taking, helpfulness, and a willingness to reconcile and forgive.

Cairone and Mackrain report that due to toxic stress, mis-expression of these nascent strengths may occur during conflicts that the young child experiences. This understanding is a key challenge for the adult when encountering challenging behaviors. The adult looks at conflicts as teaching opportunities. There are consequences when

children have conflicts, of course, but for the adult as well as the child. The consequence for the adult is to use a guidance approach that calms all down, mediates the conflict, and teaches what new skills the child can learn at that time, after having calmed down. The consequence for the child is to come to accept that the adult is there to help, and to move forward with emotional and social skill-building.

Gartrell and Cairone illustrate that in relation to other adults, the guidance approach starts with teamwork by staff in the use of coordinated leadership to enhance the child's resilience and empower the child to use emotional and social attributes and skills. Two or more staff persons working as a team often can accomplish what neither one can alone. The focus of collaboration includes work not just directly with the child but also with the child's family. Cairone and Mackrain state that guidance for healthy emotional and social development involves a triad relationship of early childhood professionals, the child, and key family members.

Marilou Hyson and Heather Biggar Tomlinson emphasize that professionals build relationships of mutual acceptance and trust with family members no less than with the children in their care. Using the team approach, they work to overcome occupational, social, and cultural factors that may make both family engagement with the program and productive family-teacher relationships difficult. If individual children are experiencing high stress levels, family members themselves tend to be dealing with adverse life circumstances. Locating and utilizing resources to effect a comprehensive approach with child and family member(s) is an important strategy for early childhood educators. Staff work actively with family members to cultivate mutual trust, and they support the adults in the parenting role.

Social Dimension

In the field of early childhood education, guiding behavior almost always entails group settings and guidance of children within the context of the

group. The use of developmentally appropriate practice maximizes the likelihood that good guidance with individual children extends to all in the group. Terms such as *inclusive communities* and *encouraging classrooms* define the early childhood environment in which all children are supported sufficiently in their emotional development so that they can succeed in social interactions and relationships with peers and adults.

The early childhood professional guards against any individual in the community being subject to rejection and stigma. Avoiding embarrassment is key. In particular, children vulnerable to rejection tend to be active, rambunctious, and sometimes aggressive in their daily behaviors. Caring professionals reject the "80% rule," that if 80% of children in a group are behaving productively and getting along that is "good enough." Educators make professional modifications to the education program, daily schedule, group expectations, and guidance practices to make the community inclusive and encouraging for all.

Recognized practices that widen the circle of developmental appropriateness typically include reducing teacher-directed large groups and activities that require children to sit down and follow directions. Copple and Bredekamp found that active programs, with many choices and a minimum of adult direction, tend to proactively engage young children. Family groups within the class—stable "pods" of a small number of children (typically of different ages) who might eat, rest, and do daily activities together with the same adult leader—enhance relationships among peers and with primary caring adults. Such programs empower mastery (intrinsic) motivation and active lifestyles.

Practices that build encouraging learning communities include regular large-group meetings; predictable routines with intriguing (not chaotic) variations; and attractive, culturally relevant, age-appropriate settings that offer many choices in distinct areas. Group meetings, going beyond traditional circle times, offer opportunities even for very young children to have meaningful community input and to create a climate of mutual respect.

Such practices diminish the occurrence of classroom-caused conflicts that children fall into as a result of frustration, restlessness, and boredom.

Practices that early childhood professionals use in guidance interventions during conflicts—expressed disagreements between people—typically include crisis management, guidance talks, conflict mediation, and class meetings.

Crisis management techniques are used when children have lost emotional control in order to prevent harm, calm parties down, and restore equilibrium so that other guidance interventions can be effectively used. Using firm but friendly practice to help children find a place and time to calm down is central. Sometimes the place is on the teacher's lap.

Guidance talks are used when individual children have experienced a conflict resulting in serious disruption and/or harm to others. After restoring calm (and as soon as the adult can make the time), she or he talks empathetically with the child about how the child saw the conflict, what the consequences of the conflict were, how the child can help others feel better, and what the child can do differently next time to minimize harm and disruption.

Conflict mediation involves the adult using measured methods of leadership when a small number of children have experienced a serious conflict. Typically, the adult uses an interactive procedure to (1) restore calm, (2) identify how each child saw the conflict, (3) brainstorm inclusive solutions, (4) get agreement on a solution and try it, and (5) follow up, such as by having individual guidance talks, reinforcing the children's achievement at resolving the problem, and reiterating alternative non-hurting responses to use in the future.

Group meetings can be held not just as practice to build inclusive settings but also as a situational strategy to resolve conflicts that have become noticeable to many in the group. An example is when a term like *butthead* catches on. The early childhood professional adapts the steps of conflict

mediation described earlier, perhaps skipping step 1 if unnecessary, and perhaps blending steps 3 and 4. Group meetings can be held to resolve such problems as forgetting safety considerations on a group walk or excluding children from joining others at play. They offer positive alternatives to traditional "group punishments," which tend to cause negative dynamics among children and with adults. A few established guidelines often help, such as, "We respect each other's ideas."

Guiding behavior, or guidance, has two dimensions, focusing on the individual child and children in a group setting. In early childhood education the intent of guiding behavior is to empower and facilitate the positive emotional and social development of each child in the group. A key consideration in using guidance is to model and teach an appreciation of the worth of all individuals who are a part of the caring community of young children and adults living and working together.

HEAD START

Head Start is a federally funded program begun in 1965 and aimed at providing services to low-income children. A total of nine presidential administrations have kept Head Start moving forward through reauthorizations, appropriation of funds, and legislation to increase access and quality. Head Start serves as a model for economic investment and early childhood education (ECE). Head Start's contribution to the field of early childhood runs deep as it has developed systems that regulate monitoring, program structures, family engagement, health, and learning in comprehensive ways.

Since its inception, Head Start has made various efforts to remain current and respond to research evaluating its outcomes. This entry briefly summarizes the history of Head Start and provides an overview of the chief components that define the program and how they translate into services for children and families.

History

The Head Start program has been touted as one of the most innovative and steady educational policies ever to be implemented. Despite critical research that cast doubt on its effectiveness, Head Start legislation has been kept alive for 50 years and remains one of the only successful remnants of the Great Society policies of President Lyndon

B. Johnson. The Head Start program was born under the direction of Sargent Shriver, who served as Johnson's director of the Office of Economic Opportunity, and the chief general of the War on Poverty.

Upon uncovering that the largest distribution of poverty in the United States in 1964 fell among children under the age of 12, Shriver decided that the most strategic way to wage a war against poverty was to focus it on children by way of a summer program in 1965. To construct the program, Shriver enlisted a panel of experts including Robert Cooke, a pediatrician at Johns Hopkins University, and Edward Zigler, a professor of psychology and director of the Child Study Center at Yale University.

As the U.S. government responded to research findings on the impacts of poverty on education, the Head Start summer program aimed at increasing IQ scores by impacting not only the children directly, but also their communities and neighborhoods. Included in Head Start's original mission was to offer a comprehensive program that would address children's emotional, social, health, nutritional, and psychological needs. From its inception, Head Start's underpinnings were based on a promise to be culturally responsive to its clients as well as to ensure a collaborative effort between the program and the communities in which they served children.

In the summer of 1965, the government funded Head Start at a rate of \$185 per child. The

program was held in dormant school buildings serving 561,000 children, with the total appropriation at this time being \$96.4 million. Teachers who lacked training in early childhood were quickly hired to fill the job openings. Though the program was under way, the expert panel that helped to develop it was not entirely happy with the structure of the program's routines. Lack of space when schools resumed their session quickly presented a problem. As the program stretched from a 3-month program to a 10-month program in 1966, securing sufficient staff also became a challenge.

During its early days, Head Start fell under the jurisdiction of the Office of Economic Opportunity. There were no legislated standards in place and enrollment grew to serve over 700,000 children. By 1981, Head Start as a summer program was completely dissolved and all programs became year-long. In addition, data collection and reporting were critical components of the program. Beginning in 1968, Head Start issued reports on impacts and descriptive information about participation and program impacts.

In 1994 the Reauthorization Act of Head Start established Early Head Start to offer services to children under the age of 3 and to pregnant women. Migrant Head Start began in the late 1960s to ensure that families of farmworkers also had access to quality child care services. In 1998 the federal government commissioned a study to determine the extent to which seasonal farmworkers had access to Head Start services and found that only 19% of eligible migrant and seasonal children were being served. In response, additional funds were appropriated in 2001 to the Migrant and Seasonal Head Start (MSHS) program. Federal funding for Head Start is now administered by the Administration for Children and Families (ACF), a division of the Department of Health and Human Services.

Infrastructure

Head Start regulations are extremely comprehensive and oversee all aspects of programmatic delivery and quality systems, including how children are recruited and selected and how they are cared

for. The following section briefly outlines some of the major areas that comprise the structural elements of Head Start. These elements define Head Start and ensure its delivery is comparable from site to site and state to state.

Eligibility Requirements

To be considered eligible for Head Start, a child must be at least 3 years of age and meet one or more of the following criteria: his or her family's income is below the poverty line, the family is eligible for other public assistance programs, or the child is homeless or in foster care. While there is some allowance for children who do not meet these requirements to be included, the vast majority of children are selected on the basis of these requirements. Part of the legislation also regulates the acceptable paths through which a grantee is allowed to access this information about families for determination of eligibility.

Reporting and Monitoring

Head Start, in part, owes its success to its systematic and carefully executed monitoring systems. From regulations about reporting on enrollment and demographic data, spending, and attendance, to mandates about classroom quality observations and teacher development, all are collected and reported on yearly. All of these data are reported by way of the program information reports that are available for each year and that include comprehensive data on the services, staff, children, and families served by Head Start and Early Head Start programs nationwide. Also available are program service reports that provide monitoring information on grantees.

Since 2012, Head Start adopted the Classroom Assessment Scoring System (CLASS) as its measure of quality in classrooms and as springboards for professional development. Since that time, the Office of Head Start uses CLASS on a random sample of classrooms to determine grantee-level quality in yearly reviews. Scores are also reported in separate reports on CLASS scores annually, as well as in the Program Service Reports. Data sets

for each of these reports are available to the public on the ACF Early Childhood Learning and Knowledge Center website. In addition, numerous research studies have been commissioned through the Office of Planning, Research, and Evaluation to encourage best practices for Head Start. All of these studies have led to further development of Head Start operations and innovations over time.

Program Options

Head Start programming is available to families by way of either center-based or home-based options. Center-based options vary in terms of offerings related to days per week and hours of operation, but remain the more widely used option, with 96% of Head Start services provided in centers in 2014. Days per week for services range from 4 to 5 days per week, and hours range from less than 6 to more than 6 hours of operation. Center-based programs serving children for 5 days per week for 6 hours represent the largest share of program models, with 43% of programs operating in this way.

Head Start Workforce

The Head Start workforce is a reflection of its mission to engage with the community. In 2014, Head Start reported that parents of children (both those currently enrolled and former students) comprised 24% of the overall staff. The Office of Head Start in the ACF regulates the process for recruitment, hiring, qualifications, and monitoring of all staff covered by each of the program elements, including education, health, parent involvement, and social services.

As of September 2013, at least half of the teachers in each Head Start preschool program had to have a bachelor's degree in early childhood education or an advanced degree in any subject, and coursework equivalent to a major relating to ECE with experience teaching preschool-age children. In 2014, the Office of Head Start reported that 58% of teachers in center-based preschool programs had a BA while 13% had an advanced degree in ECE or a related field. An additional

25% of Head Start preschool teachers had an associate's degree in ECE or another related field. This mandate has shown Head Start's commitment to research, highlighting not only the importance of baccalaureate degrees for teachers in preschool, but also the importance of specified training in ECE as a prerequisite.

National Centers and Technical Assistance

In efforts to build capacity at both the site and individual levels, the Office of Head Start provides professional development to staff and programs through a three-pronged approach. Included are the direct funding of grantees, a state network of technical assistance, and the provision of six national centers addressing topics of quality teaching and learning, cultural responsiveness, health, parental and family engagement, program management and fiscal operations, and Early Head Start. In addition, the Early Learning Mentor Coach Initiative was launched in 2010.

Elements of Services to Children and Families

Head Start's goal is to transition children to kindergarten by preparing them alongside their families to be successful. To do this, Head Start aims to foster learning by addressing children's needs in a highly individualized and responsive manner. Teachers are guided through a framework and ongoing formative assessment of child progress. The following section provides a brief overview of each of Head Start's elements for services provided to children and families in order to ensure school readiness.

Educational and Child Development Services

Head Start's approach to education and child development persists as a key aspect of its mission. The National Center on Quality Teaching and Learning, administered through the ACF, has provided a Framework for Effective Practice that includes environments and interactions, research-based curricula and teaching practices, ongoing

child assessment, and highly individualized teaching and learning. All of these are guided by the Head Start Program Performance Standards and the Head Start Child Development and Early Learning Framework that help to align program goals and school readiness goals to each other. The Head Start Child Development and Early Learning Framework covers 11 domains, including physical development and health, social and emotional development, creative arts, approaches to learning, literacy knowledge and skills, logic and reasoning, mathematics knowledge and skills, science knowledge and skills, social studies and skills, and English language development. In addition, grantees are mandated to choose a research-based curriculum that closely aligns with this framework.

While specific curricula are not prescribed, guidance on how to choose a curriculum and what makes this important are offered to grantees by way of various resources accessible online. Head Start suggests that curriculum be child-driven and responsive to children's interests. Guidance on selection of child assessment tools is similarly provided. Head Start mandates that child assessments be ongoing. The assessments must clearly be well matched to the framework on education and child development.

Teacher development by way of coaching is also an integral piece of Head Start's model. Through coaching and use of CLASS, Head Start seeks to continuously professionalize its workforce. Teacher development in Head Start is guided by a cyclical approach to improving teacher practices through observing, planning, and reflecting on practice with a coach. Data on this process are also recorded and reported.

Health Services

Head Start's commitment to health and safety is based on research that shows that health and safety have impacts on child development. The partnership with families is crucial under these services, as a main part of the goal encompasses the identification, treatment, and continued attention to health- and safety-related issues. Health services in the Head Start model encompass safety

and injury prevention, physical health, nutrition, oral health, mental health, health services management, health literacy, family engagement, and healthy active living. In 2014, Head Start saw a rise in children who had immunizations, health insurance, and ongoing medical and dental care.

Social Services

In addition, Head Start reports that 33% of the 45,000 families who experienced homelessness in 2013–2014 found housing during the year. Other assistance received by families included subsidies, utilities, repairs, and job training/adult education. In 2014, Head Start reported that 74% of families received at least one service.

Parent, Family, and Community Engagement Services

Parent, family, and community engagement have been a cornerstone of Head Start since its birth in 1965. In 1970, Head Start mandated parent participation by way of a policy that required parents be involved in all program decision making and program operation through parent committees, policy committees, and policy councils.

In 2011, the ACF released the Parent, Family, and Community Engagement Framework, a research-based guide for families and programs including markers of progress for both programs and families. Most importantly, the document helps to guide and coach families about how to involve themselves in the education of their young children as well as how to advocate for them. Both of these goals are intended to help families become aware of their ability to be active agents in their children's academic success.

Cultural and Linguistic Responsiveness

The largely marginalized groups that Head Start continues to target remain those who are most at risk for poor school performance. The rising population of Hispanic students has drawn attention and sparked action for educators, researchers, and

policy makers alike. Consistent with national demographic reports about numbers of Hispanics, in 2014 the Office of Head Start reported that 38% of participants are Hispanic and 25% of the families it serves speak Spanish at home.

Since its birth, Head Start has sought to address issues of linguistically diverse learners and in 1972 included language in the Head Start Program Performance Standards requiring that children's cultural identity be built upon and also that staff speak to children in their home languages. In 1991, Head Start released its Multicultural Principles to ensure individualization of experiences for diverse families. These were updated in 2010. In 1996 the Head Start Program Performance Standards expanded to include over 20 standards that range from respecting the home language and cultural backgrounds of children and families to requiring programs to address the needs of dual language learners and their families across multiple services and systems. Head Start reports that over half of the dual language learners that it serves have teachers who are speakers of other languages.

Research on Head Start

Evaluations of the impacts of Head Start are a critical aspect of its long history. Early evaluations tracked impacts on children's IQ, while more recent evaluations have focused on vocabulary growth, early math skill development, and social and emotional skills. While many studies have asserted positive impacts of Head Start, others have pointed out methodological flaws in this research, raising doubt about claims on fade-out.

The Head Start Family and Child Experiences Survey (FACES) seeks to assess children on outcomes across all the focus areas of the program through direct assessments, interviews, and classroom observations. The data from this report allows Head Start to look at overall program quality and its relationship to child outcomes. In the most recent report, Head Start children showed growth in language, literacy, writing, and early math skills. Social and emotional skills also showed gains, including decreases in problem behaviors. Additionally, Head Start provides numerous

reports to Congress on different aspects of programming including evaluations of particular program elements and spending.

Conclusion

Head Start's resources and support services have served as a model as other systems for administering early childhood education have emerged. It is the only initiative directly funded by the federal government to give free access to early childhood care and education. Its commitment to the whole child, families, and communities has been crucial in its staying power as the most powerful advocates have been the families themselves.

HEALTHY CHOICES AND YOUNG CHILDREN

The early years of life are a critical time of growth and development. Young children are influenced by their caregivers, environment, and learning experiences. This entry provides information about the aspects of and barriers to healthy choices by young children. A summary of an ecological system theory is given, followed by examples of interventions focused on promoting health and wellness.

Young children learn about healthy habits from their parents and other caregivers. Adults determine most aspects of a child's diet and model different levels of physical activity. Health habits acquired during early childhood are important because they are predictive of future dietary and activity behaviors. Unhealthy food choices and sedentary lifestyles in young children can contribute to childhood obesity and future health concerns such as type 2 diabetes and heart disease. Obesity is also associated with psychosocial impacts such as depression, bullying, and social exclusion. Therefore, fostering positive approaches to eating healthy foods and engaging in physical activity can increase children's ability to make healthy choices.

Research

There are many factors that influence health. The increase in the incidence of childhood obesity has led to increased efforts to determine factors that promote health and wellness. Childhood obesity is a complex issue resulting from multiple factors, including, but not limited to, genetics, altered self-regulation, media exposure, parental behaviors, food choices, levels of physical activity, and sleep patterns. Specific genetic components such as metabolic rate, gender, and ethnicity predispose some children to be overweight. Researchers have given special attention to populations that have been identified with higher levels of health risk including African Americans, Latinos, Native Americans, and low-income families. Programs and policies correlated with improving the health of young children and their families are being developed based on this research.

Research findings related to young children and healthy choices include the following:

- Adult modeling of positive attitudes and behaviors related to health can increase children's frequency of healthy eating and physical activity behaviors.
- Young children are more likely to consume healthy foods when they help with preparing food and are given repeated exposure to new foods.

- Young children who regularly eat the evening meal with their family, obtain adequate nighttime sleep, and have limited screen viewing time are less likely to be obese.
- Adults promote physical activity in young children by being physically active and offering children increased opportunities for physical activity.
- Children who develop proficient motor skills at a young age are more likely to engage in physical activities throughout their lives.
- Barriers to healthy food choices include availability and affordability of healthy foods, lack of time to cook, poverty, food insecurity, parenting styles, lower levels of health literacy, and media messages promoting unhealthy eating.
- Barriers to physical activity include lack of recreational areas such as playgrounds and cycling lanes, neighborhood safety, time, parents' physical limitations or health issues, and media messages promoting sedentary behaviors.

Theory

Urie Bronfenbrenner's ecological systems theory is commonly cited as a conceptual framework for defining environmental influences on young children's food and physical activity choices. Young children are directly influenced by the people in their lives and the environment in which they live. Their immediate environment includes the practices, economics, and culture of their family or other caregivers. Likewise, the community environment contributes to societal practices related to eating and physical activity levels. Some communities foster sedentary behaviors and overeating due to the lack of access to recreational physical activities and the higher availability of low-cost, energy-dense, nutrient-poor foods. The interaction between the immediate environment and the community directly and indirectly influences young children and their health choices.

Interventions

Numerous programs and policies are being implemented to promote healthy choices during the early years of life. One of the best approaches to

addressing healthy lifestyles is through programs targeting the entire family. Educational programs have focused on improving food choices, increasing physical activity, and reducing screen time. Interventions have included having children grow gardens, taste new fruits and vegetables, and learn how to listen to their internal hunger and fullness cues to self-regulate their food consumption. Programs have been designed to teach children fundamental motor skills and to create opportunities for children and families to be physically active together. Moderate changes to food choices and physical activity levels have been shown to make a difference to children's health.

Communities have made environmental changes to promote healthy choices such as opening school playgrounds for families to engage in physical activities together and creating safe streets with walking paths and cycling lanes. Additionally, efforts have been made to increase the availability and decrease the cost of fresh fruits and vegetables. Schools and child care facilities have altered menus and are serving healthier food options. These interventions and others are promoting young children's healthy food and activity choices.

HEALTHY ENVIRONMENTS FOR SOCIAL-EMOTIONAL DEVELOPMENT

Social-emotional development has been widely recognized as an important component of early childhood education, and includes children's experience, expression, and regulation of emotions, as well as abilities to establish and maintain positive relationships with others. These social-emotional competencies contribute to children's school readiness, allowing children to enter school prepared to engage and learn with peers and teachers. According to a bioecological perspective, children's interactions with their environments impact their development. Thus, in considering healthy environments that promote social-emotional development, this entry highlights the roles of children's temperaments and environments such as the home and family, child care and schools, and communities and cultures.

The Child and Temperament

Temperament refers to a person's emotional, attentional, and behavioral styles or traits. Children's temperaments are evident in infancy, and these traits are carried forward into adulthood. Effortful control and negative affectivity are two important temperament factors that contribute to children's self-regulation or emotion regulation and adjustment. While temperament

represents the basic building blocks for complex behaviors and personality, children's experiences and interactions with others and with their environments shape children's developmental trajectories and outcomes.

Family Environments and Parenting

Early social experiences and the family system contribute to the development of children's social-emotional competencies, with the home environment often as one of the first and most influential contexts for young children's development. Parents' or caregivers' sensitivity to children's needs and signals are major contributing factors to children's attachment and emotional security. Emotionally secure children enter school ready to establish positive relationships with their peers and teachers. The way parents express emotions with their children also influences the emotional climate of the family. Research has consistently shown that parents' expressions of warmth and positive emotions toward their children are linked to children's social-emotional competence and positive adjustment. By contrast, parents' nonresponsiveness or expressions of hostile and harsh negative emotions toward their children are linked to children's maladjustment.

Parenting styles can be broadly classified by two dimensions of responsiveness and demandingness or strictness. Parents who are strict and unresponsive are classified as authoritarian, while parents who are strict and responsive are classified as authoritative. In general, authoritarian parenting is linked to negative, while authoritative parenting is linked to positive, developmental outcomes. And while both authoritarian and authoritative parents are demanding or strict, the type and amount of parental control over children have impact on children's healthy development. Parental control could be distinguished as structure (e.g., monitoring and limit-setting) versus psychological control (e.g., intrusiveness and coercion). Psychological control is consistently linked to negative developmental outcomes, while structure corresponds more with the strict and responsive combination

characterized by authoritative parenting that is often linked to positive development. In summary, parenting that is empathic and responsive while asserting developmentally appropriate expectations or structure promotes children's social-emotional development.

Child Care and School Environments

In addition to the home environment, many children spend substantial amounts of time in child care, preschool, or primary school environments that are major sources of socialization for children's social-emotional development. Similar to a healthy home environment, child care and school environments that are safe and responsive to children's needs and individuality (temperaments) promote their exploration and learning. Positive student-teacher relationships in which students share caring, yet respectful bonds with teachers support children's socio-emotional growth. This is achieved when teachers show genuine interest in the students' overall well-being and understand children's home environments, developmental levels, and other factors that may influence children's behaviors in the classroom.

Early peer relations and peer play offer important opportunities to hone social-emotional skills such as communication, prosocial behaviors, cooperation, and problem solving. Bonding in the classroom can be created through structuring learning environments that support group projects and small-group lessons. Teachers can also create a positive and supportive learning environment by praising children for prosocial, respectful, and appropriate behaviors in the classroom. Negative behaviors could be prevented or reduced when directions are clearly stated in positive, simple language—stating what you expect students to do instead of what not to do.

In summary, child care and school environments that are safe and responsive to children's needs and offer positive student-teacher and peer relationships provide children with optimal social-emotional growth.

Communities and Cultures

In addition to the day-to-day experiences that children have in the family and school contexts, the communities and cultures in which children are raised are influential in children's social-emotional development. One example is the temperament traits of shyness and behavioral inhibition, where cultural meaning and societal expectations may influence the acceptability of these traits in children. Children who are raised in communities or cultures that are more individualistically oriented are often encouraged to engage in autonomous and self-assertive behaviors. In highly individualistically oriented communities or cultures, shyness or behavioral inhibition might be negatively viewed or evaluated. By contrast, the same temperament traits might be encouraged and preferred in communities or cultures that are highly collectivistic because reserved or restrained behaviors are less likely to disrupt group harmony and group functioning. In this case, children with temperament traits of shyness or behavioral inhibition are less likely to be negatively evaluated and may even be praised or rewarded. However, community and cultural values and norms are dynamic, not stagnant. For example, research on Chinese American immigrant families shows that parents who support their children's autonomy development promoted social-emotional competencies such as emotion regulation and adaptive skills. And while community factors such as poverty and exposure to violence put children at risk for poorer social-emotional development, sensitive and responsive caregiving could protect and promote children's emotional self-regulation competencies.

Conclusion

Children are born with unique temperaments, and their experiences in environments such as the family, child care or schools, communities, and cultures jointly influence their development. Parents, teachers, and peers contribute to children's development of social-emotional competencies such as emotional self-regulation. Environments that are

safe, positive, and responsive to children's individuality (temperaments) and developmental needs support children to grow into healthy, autonomous, socially responsible, and competent people.

HIGHLY QUALIFIED EARLY CHILDHOOD TEACHERS

Highly qualified teachers embody the highest standards of the early childhood profession. They are able to establish warm and caring relationships with children, promote children's curiosity and love of learning, and foster their development and learning. Standards defining teacher qualifications and competencies are created and assessed by professional organizations, defined in state documents for licensing and regulating teachers, and described in policy documents that outline competencies for practitioners. Although there is no universal agreement within the professional or research literature to define what constitutes a highly qualified teacher, research suggests that highly qualified teachers positively affect children's developmental and learning outcomes and overall program quality. This entry first discusses the credentials available to early childhood teachers, the professional standards that must be met to earn these credentials, and state requirements for preschool teachers to be considered "highly qualified." It then discusses academic degrees for early childhood teachers and research on their significance in preparing teachers for the early childhood setting.

Credentials as Indicators of Highly Qualified Teachers

Credential is the broad term that refers to a specialized qualification that includes certificates and licenses, the official documents or authorization to practice. Examples include the Child Development Associate (CDA) national credential, state teaching licenses or certificates, and National Board for Professional Teaching Standards certification. Credentialing systems apply to teachers of all children. They drive the standards of programs offering coursework leading to the given credential, license, or certificate, setting the bar for quality practice. However, the content of programs that lead to the credential is not uniform, reflecting a lack of consensus in the field regarding the

required knowledge and skills for today's early childhood teachers.

Professional Standards for Highly Qualified Teachers

Professional organizations have identified standards for programs that prepare early childhood teachers. These standards are operationalized as competencies that can be observed and assessed, serving as the basis for awarding credentials by the program. Most of the standards and competencies across early childhood organizations are similar, suggesting that highly qualified teachers share more commonalities than differences. The National Association for the Education of Young Children (NAEYC) standards are used by the Council for the Accreditation of Educator Preparation (CAEP), formerly the National Council for the Accreditation of Teacher Education (NCATE), to accredit initial and advanced early childhood teacher education programs. These standards focus on the competencies students develop in the areas of promoting child development and learning; building family and community relationships; observing, documenting, and assessment children; using developmentally effective approaches to connect with children and families; using content knowledge to build meaningful curriculum; and becoming a professional. These same standards are correlated with the CDA subject areas for teachers pursuing this credential.

The National Board for Professional Teaching Standards (NBPTS) offers the Early Childhood Generalist certification to teachers with 3 years of experience who hold a teaching license as required by the state in which they work. Teachers working with children ages 3 through 8 years can complete the competency-based process to earn recognition as a National Board Certified Early Childhood Generalist. Standards for this credential reflect the competencies identified by NAEYC and NCATE.

The National Association for Early Childhood Teacher Education (NAECTE) identifies highly qualified teachers as having specialized training in early childhood focusing on birth through 8 years of age. According to NAECTE, teachers with a

sound preparation in early childhood are prepared to apply knowledge of child development and teaching strategies to match the way young children learn. These teachers are able to meet the social and emotional needs of young children in ways that nurture development of critical social skills and prevent or address behavior problems; understand that young children's thinking is qualitatively different from that of older children; know how to scaffold children's learning to help them become successful in meeting school expectations; and understand the language and literacy development of children to better support it.

State Standards for Highly Qualified Teachers

The National Institute for Early Education Research (NIEER), in comparing 10 critical areas associated with quality in preschools, identifies four standards related to teacher credentials and training as a point of comparison across the states. State preschool policies are evaluated on whether their programs require teachers to have a bachelor's degree, whether they require teachers to have specialization in preschool education, whether they require assistant teachers to have at least a CDA or equivalent credential based on coursework, and whether they require teachers to have at least 15 hours of annual in-service training.

Early childhood teachers working in public school settings are considered "highly qualified" if they hold the requisite degree and teacher license required by the state and meet the No Child Left Behind Act requirement to hold a bachelor's degree, have state certification and/or licensure, and demonstrate they know each subject that they teach. As a result, there is wide latitude across states for how "highly qualified" is defined and operationalized.

Academic Degrees as Indicators of Highly Qualified Teachers

Teaching young children is a cognitively complex endeavor. Highly qualified teachers are able to skillfully combine explicit instruction with warm interactions that lead to nurturing, trusting

relationships with individuals. These teachers provide responsive feedback, verbal engagement, and cognitively stimulating experiences intentionally designed to promote children's learning within an environment that is neither too regimented nor too unstructured. Children are given choices to explore and play, engaged through multiple input channels within natural settings that are comfortable and predictable.

Because good teaching depends on the teacher's knowledge and skills, highly qualified teachers complete formal, specialized education. The research on the significance of a degree to teach in early childhood has come under close scrutiny. However, it is clear that teachers who have more formal teacher preparation to work with children during the birth to age 8 period tend to provide more appropriate and responsive interactions and tend to have more significant learning and developmental outcomes for children. Highly qualified teachers have content knowledge in the academic disciplines that serves as a foundation for pedagogically adapting that knowledge for instruction with young children. Through teacher education programs, highly qualified teachers learn the strategies for designing curriculum, observing and documenting children's learning and development, evaluating children's progress, and adapting curriculum and environments to meet the needs of all children, including those children who are culturally and linguistically diverse, and children with diverse physical and cognitive abilities and limitations. Through supervised field experiences in multiple settings, highly qualified teachers interact with children and other professionals to gain skill in reflective practices and to systematically study their own teaching.

HIGH-QUALITY EARLY EDUCATION, LONG-TERM BENEFITS OF

This entry discusses the long-term benefits of high-quality early education and how research findings fueled today's emphasis on improving early learning opportunities for all children. The early years of life are a time of rapid growth and development. From birth to age 5, children are constantly exploring their environment. They are learning to communicate verbally, control body functions, self-regulate their emotions, and interact with others. These early years provide the foundation for healthy development and future learning. As a result, the quality of care and education that young children receive during these formative years will significantly influence the trajectory of their lives.

Recognizing the positive impact of high-quality early education, federal, state, and local governments are working to improve early education for all children. This emphasis on early learning, however, was not always a legislative imperative. For many decades government agencies and communities focused only on K–12 education, asserting that early learning was the responsibility of families.

Families, however, had few options when considering preschool education for their children. Furthermore, the opportunities for *high-quality* preschool education were limited by socioeconomic status and geography; in other words, the income level of families and where they lived were often barriers that prevented access to high-quality early education.

Although more early education options are available today, from home-based care and community centers to public preschools, families continue to find it difficult to make an informed decision. Often they do not know what constitutes “high-quality” early education and as a result are not sure what is the best early learning environment for their children.

“High-Quality” Early Education

The National Association for the Education of Young Children (NAEYC) has been a strong advocate for high-quality early education since it was founded by Patty Smith Hill almost 90 years ago. NAEYC provides an accreditation process that is rigorous and based on research-informed best practices. Thousands of early learning centers across the United States strive to meet the high standards of excellence and receive NAEYC accreditation. NAEYC states that early childhood education must adhere to the principles of excellence, access, equity, diversity, and accountability.

High-quality early education programs are multifaceted and are designed to serve both children and families. The following list is not comprehensive, but it highlights basic characteristics of high-quality early education programs.

- The early learning program is designed using research-based best practices.
- Clearly defined early learning standards guide implementation of the program.
- The curriculum is developmentally appropriate and targets the *whole child*: supporting cognitive, social, emotional, and physical development.
- The learning environment is engaging with multiple interest areas: nature center, art center, music center, literacy center, math center, puppet/drama center, block center, dramatic play center.
- Class size is small, enabling teachers to be responsive to and supportive of children’s learning needs.
- Children’s development is monitored and regularly assessed to ensure positive educational, health, and social outcomes.
- Families are involved with program planning and evaluation processes.
- The teachers are well trained and the program provides them with continuous improvement opportunities through intensive supervision, professional development, and instructional coaching.

Research clearly indicates that providing high-quality education for children from infancy to age 5 yields significant long-term benefits. For over 50 years researchers have studied early education. Their findings address both the characteristics of high-quality learning environments for young children and the benefits garnered by the children who attend high-quality programs.

One well-known longitudinal research project, the HighScope Perry Preschool Study, followed 123 children from preschool to adulthood. The researchers found that children who were enrolled in high-quality preschool programs were more likely to graduate from high school, own homes, and have longer marriages. Furthermore, children who attended high-quality preschool programs ultimately earned up to \$2,000 more per month than children who did not have this early learning opportunity.

Another study, the Abecedarian Project, found similar results. Researchers followed 111 children from program entry (infancy) to age 21. They wanted to determine the individual outcomes of a full-day (6 to 8 hours), year-round, high-quality early education program. Their findings indicated that children who attended high-quality preschool programs (infancy to kindergarten) were less likely to repeat grades or need special education placement. Growing up, the children were less likely to become teen parents or get into trouble

with the law. Additionally, as adults, they were more likely to have a skilled job.

The Chicago Child Parent Center Study (CPC) replicated the HighScope Perry Preschool Study, but also focused on the benefits gained if the parent, as well as the child, received services. The CPC study had a relatively large sample size. The researchers followed the development and educational progress of 989 children into adulthood and confirmed the long-term findings of the HighScope Perry Preschool Study and the Abecedarian Project. Data from this study confirmed that children enrolled in high-quality early education programs had higher graduation rates from high school, fewer referrals for special education placement, and a lower rate of juvenile arrest. A cost-benefit analysis of the data collected provided significant results that support the expenditure of public dollars for high-quality early education. The data suggested that for every dollar invested in a child, the purely economic benefit was a \$7.10 return to society. The economic benefit to society included savings on special education services, reduced criminal justice system expenditures, and increased tax revenues once the children were adults.

Beyond these three major research studies are hundreds of additional research projects conducted by researchers throughout the United States. When the findings are synthesized, there is a body of evidence that clearly supports the long-term benefits of high-quality early education. The multiple research studies, however, used many different research designs and hypotheses. Thus, when considering the findings it is most effective to blend the data using a statistical process called a meta-analysis. The research literature cites multiple meta-analyses that summarize the findings from numerous early learning studies. These findings support the following conclusions:

- Early care and education programs have positive effects on young children's cognitive and social development, and these effects can impact future learning.
- Research finds that the early learning programs with the greatest impact on future outcomes for

children are the most educationally intensive and expensive.

- Although all children reap benefits from high-quality preschool education, research suggests that children from economically disadvantaged homes show the greatest gains.
- Both half-day and full-day programs have positive benefits for children, but only full-day programs are linked to economic benefits for families, due to increased parental employment.
- State and local prekindergarten programs with high standards provide the greatest benefits for children and families. These high-quality programs can be implemented successfully in public or private schools.
- Research indicates that high-quality early education programs decrease grade repetition and referrals for special education.
- Graduation from high school is linked to high-quality early education.
- Research indicates that high-quality early education programs impact positive social behavior and decrease teen pregnancies.
- Data show a link between high-quality early education programs and a reduction in criminal activity.
- Research studies support the connection between high-quality early education and increased adult employment and income.
- Multiple cost-benefit analyses conclude that high-quality early education programs not only achieve important learning outcomes, but are sound public investments.

Conclusion

Multiple research studies support the importance of high-quality early education for all children. Data clearly indicate that well-designed programs that are implemented with fidelity provide long-term benefits. Evidence shows that high-quality, robust early learning experiences not only enhance children's growth and development, but also benefit society as a whole. Multiple cost-benefit analyses support the economic advantages of early education, finding that for each dollar spent on quality early education,

society receives approximately a \$7 return on its investment. Investing in quality pre-K education has the potential to improve long-term outcomes for children and the citizenry of the United States.

HighSCOPE

HighScope is the name of the educational research foundation that developed and disseminates the HighScope Curriculum for use in programs for children and conducts studies of the effects of such programs. This entry describes its mission,

vision, programs, and studies. It describes the preschool, infant–toddler, elementary, and youth versions of the HighScope Curriculum, HighScope’s professional development model, the evidence for the validity of the curriculum model, and HighScope’s program implementation and child development assessment tools. It describes HighScope’s research studies on other early childhood programs and settings. HighScope is remarkably well-known; a Google search of “High/Scope” (the slash was dropped in 2009) in March 2014 found 95.8 million results.

HighScope Educational Research Foundation

HighScope Educational Research Foundation is an independent, nonprofit early childhood educational research and development organization founded in Ypsilanti, Michigan, in 1970 by David P. Weikart and his associates. They coined the term *HighScope* to signify the organization’s high aspirations and broad scope of interest. To carry out its mission of lifting lives through education, HighScope Foundation develops curriculum models and assessment tools, provides professional development opportunities to learn these models and tools, conducts research on their validity and the validity of other early childhood settings in contributing to children’s development, publishes books and materials, and communicates with its various audiences. Its vision is a world in which all educational settings use active, participatory learning so everyone has a chance to succeed in life and contribute to society. Its primary focus is programs and settings serving children from birth to age 8.

The HighScope Curriculum

The HighScope Curriculum is a system for adults to support children’s active learning and development. Weikart and his colleagues first developed the HighScope Curriculum for use in the Perry Preschool program and first published it for general use in 1971. HighScope Foundation staff regularly update the curriculum and apply it to new domains. The central feature of the curriculum is

respect for the thinking of children and their capacity to initiate and carry out their own learning activities. HighScope has developed and spread its educational model for young children in preschool programs, infants and toddlers in home visit programs and child care settings, children in elementary schools, and teenagers in summer camps and after-school programs. Studies by HighScope and others have confirmed the short-term and long-term effectiveness of these applications.

Preschool Curriculum

The HighScope Preschool Curriculum is a system for supporting the active learning and development of young children 3 to 5 years old. It was originally developed by staff of the Perry Preschool program, drawing on the latest child development theory and research of the time. The curriculum starts with a strong commitment to young children as thinking, responsible human beings and focuses on active participatory learning. Adults ask children what they want to do and help them develop essential knowledge and skills based on the children's own interests. Adults provide open-ended materials and interact with children to support their exploration and extend their learning. Adults arrange the classroom into activity areas to support various kinds of learning in all content areas. They establish a daily routine that allows children to plan and review their own learning activities. They focus on key indicators of all aspects of children's development—approaches to learning; language, literacy, and communication; social and emotional development; physical development, health, and well-being; mathematics; science and technology; social studies; and the arts. Teachers work with parents to apply curriculum principles and practices with children at home as well as in the classroom. In all sorts of early childhood programs and settings, teachers or observers assess program quality with HighScope's Program Quality Assessment and assess children's development using the Child Observation Record.

While retaining its basic educational orientation and practices, HighScope continually updates its curriculum and training materials to incorporate

the latest research on early development and effective education. Reflecting these updates, in 2012 HighScope released the third edition of its preschool curriculum manual, titled *The HighScope Preschool Curriculum*. A condensed version, *Essentials of Active Learning in Preschool*, is also available. *HighScope Step by Step: Lesson Plans for the First 30 Days* was designed especially for new users.

HighScope's curriculum and research have led to the development of a variety of assessment tools for programs and children's development. The Program Quality Assessment's various versions assess the quality of infant-toddler, preschool, family child care, and youth programs. The Ready School Assessment measures how ready elementary schools are for the children they serve.

The Child Observation Record, now called COR Advantage, assesses the developmentally significant behavior of infants, toddlers, and preschoolers. Originally designed for use with children in HighScope programs, it is now available for use with children in any early childhood program. While it is available in various formats, its principal format is online at HighScope.net. The Early Literacy Skills Assessment (ELSA) measures young children's literacy skills with questions in a storybook.

The HighScope Perry Preschool Study is the longitudinal study of the effects of a preschool program that used the HighScope Curriculum with 3- and 4-year-olds living in poverty. The program operated from 1962 through 1967 in the attendance area of the Perry Elementary School in Ypsilanti, Michigan. In this study, 123 children living in this area were nearly randomly assigned either to a program group that attended the preschool program or to a control group that attended no preschool program. The program maintained high quality, with systematic use of the HighScope system, certified teachers each serving five or six children, and weekly home visits. Data have been collected on these study participants annually from ages 3 through 11 and at 14, 15, 19, 27, and 40, with another round of data collection planned when the participants are in their 50s. Missing data have been minimal, with only 6% of data

missing across the many measures. The study found that program participants, compared to the control group, were more ready for school, later achieved greater school success, committed only half as many crimes, and attained greater adult economic success, thereby providing a substantial public economic return. These findings have been presented to many audiences, and advocacy for such programs grew. Funding for the national Head Start program has continued to grow, and most states have initiated their own state preschool programs.

HighScope conducted a longitudinal study to compare the HighScope Preschool Curriculum to the theme-based nursery school approach that was common at that time and the fast-paced direct instruction model. Sixty-eight children living in poverty were nearly randomly assigned to classrooms for 3- and 4-year-olds implementing these three models to high standards of quality. All three groups experienced average intellectual growth of 27 IQ points in their programs' first year. But in the longer term, the direct instruction group fared worse than the others: Only 6% of the HighScope and nursery school groups needed treatment for emotional impairment or disturbance during their schooling, as compared to 47% of the direct instruction group; and only 10% of the HighScope group was arrested for a felony by age 23, as compared to 39% of the direct instruction group. These findings suggest it is not enough for a preschool program to improve children's short-term cognitive and literacy skills if it does not also improve their long-term social development.

HighScope has developed specialized early childhood curriculum models for literacy, mathematics, music, and conflict resolution. The Growing Readers curriculum applies HighScope curriculum principles to young children's development of literacy. Through questions in a storybook, the ELSA assesses young children's development of four skills needed for literacy—comprehension, phonological awareness, the alphabetic principle, and concepts about print. The Numbers Plus preschool mathematics curriculum, developed and studied with grants from the U.S. Department of Education, integrates HighScope curriculum

principles with the recommendations of the National Council of Teachers of Mathematics. HighScope has also developed curriculum applications to social relations focusing on conflict resolution.

Infant-Toddler Curriculum

HighScope has developed curriculum materials for parents and caregivers of infants and toddlers on forming loving, trusting relationships with the babies and toddlers in their care. As with older children, the approach focuses on children learning through direct, hands-on experiences with people, objects, events, and ideas. Adults encourage infants and toddlers to discover their world by exploring and playing. The curriculum offers proven teaching practices that support children's development, content areas for infants and toddlers, program and child development assessment tools, and a training model that helps children implement the curriculum effectively. The book *Tender Care and Early Learning* presents HighScope's infant-toddler curriculum.

HighScope's current work at the infant-toddler level focuses on parents whose children are enrolled in early childhood programs and on caregivers in child care programs. To work directly with parents, it recommends that teachers in early childhood programs provide home visits and regular parent meetings. HighScope trains program staff and publishes materials to help them conduct meaningful and effective activities for parents. Second, HighScope provides curriculum materials and professional development services to those who take care of very young children in home- and center-based programs.

HighScope began its infant-toddler work in 1970 with its Infant Education Project. This program had professional staff providing home visits to young mothers and achieved some modest results. In the 1980s, with funding from the Bernard Van Leer Foundation, HighScope implemented the Parent-to-Parent Dissemination Project in diverse communities throughout the country. In this model, parents were trained and operated under the supervision of a professional to share

child development and parenting information with their peers in the community. The project led to the development of guidelines for establishing community-based family support programs.

Early Elementary and Youth Initiatives

HighScope's early elementary work today focuses on ready schools. It has developed and validated the Ready School Assessment (RSA) to serve as the basis of a school's improvement plan to become a ready school. The RSA is based on the research-based definition of a ready school developed in 1998 by a group commissioned by the National Education Goals Panel. It looks at how ready schools smooth the transition between home and school and strive for continuity between early care and education programs and elementary schools. It also looks at how ready schools do what all good schools do, such as being committed to the success of every child and teacher. The field test of the RSA involved 71 elementary schools in 17 states.

HighScope's Education Through Movement program is well developed and widely disseminated at the early elementary level. Its movement-based active learning process involves key developmental indicators in movement and music, the movement core, the teaching model, and active learning support strategies.

HighScope's early elementary roots are in the federal Project Follow Through, which ran from 1968 to 1995. In this project, HighScope applied its curriculum principles to the early elementary grades and helped selected school districts serving low-income children across the country use the approach. Its Follow Through research showed that the HighScope early elementary model improves school achievement. After Project Follow Through, the Bureau of Indian Affairs supported HighScope in elementary schools on reservations from 1996 to 2000. Several other elementary schools around the United States and in Mexico, the Netherlands, and Indonesia have continued to use the HighScope early elementary approach.

HighScope has developed and validated the Youth Program Quality Assessment (PQA) to

evaluate the quality of youth programs and identify staff training needs. Community organizations, schools, camps, and other youth-serving places use it. In a joint venture with the Forum for Youth Investment, HighScope formed the David P. Weikart Center for Youth Program Quality to disseminate the Youth PQA widely.

Professional Development

HighScope's professional development programs build on the idea that active learning is as important for adults as it is for children. Teachers learn through a combination of hands-on exercises, reading, discussion, reflection, and guided practice in their own program settings.

Today, HighScope offers a variety of training options tailored to the needs of teachers and caregivers serving infants, toddlers, and preschoolers in all types of settings. HighScope offers 1- and 2-day workshops that provide introductory, entry-level information or review a specific component of the HighScope curriculum. Week-long courses go deeper into how to implement various curriculum components. Multiple-week courses lead to HighScope trainer or teacher certification and the best practices early childhood staff need to run a high-quality program. HighScope offers online courses in which participants can engage from anywhere, at any time in the discussions of an e-learning community and get individual attention from the course instructor. HighScope staff and trainers participate in and make presentations at various early childhood conferences.

HighScope training is taking place throughout the world. Its training-of-trainers programs give early childhood program organizations anywhere the independent capacity to provide HighScope teacher training. These programs have enabled the establishment of teacher education institutes and centers in Canada, Chile, China, Great Britain, Indonesia, Ireland, South Korea, Mexico, the Netherlands, Portugal, and South Africa. HighScope has also provided training in Dubai, Saudi Arabia, the Caribbean, and elsewhere.

HighScope teacher training, which began in the 1960s, flourished in the 1980s with training-of-trainers

programs. In this model, HighScope builds local capacity by training agency-based supervisors in both curriculum and techniques for preparing teachers to implement the curriculum with the young children in their programs. Ford Foundation funding primed the pump for this national effort. At its high point, 1,075 trainers were training the teachers in 13,000 early childhood classrooms a year, half of them of demonstration quality.

The HighScope Training for Quality Study found a variety of evidence of the effectiveness of the current HighScope preschool education model. This study surveyed 203 certified HighScope teacher trainers, surveyed and systematically observed the classrooms of 244 HighScope and 122 comparison teachers in diverse early childhood settings serving diverse populations, and systematically observed and tested 97 HighScope and 103 comparison children in these classrooms. HighScope classrooms significantly surpassed comparison classrooms in classroom environment, daily routine, adult-child interaction, and overall quality of implementation. HighScope programs experienced significantly better supervisory and teaching practices than non-HighScope settings. Independent observers rated the HighScope classrooms as higher on the following dimensions: overall program quality, organizing and labeling the room to promote children's independence, providing diverse materials that were easily accessible to children, encouraging children to plan activities based on their interests, encouraging children to review and reflect on their actions and experiences, and using observations and open-ended questions to extend children's play. Further, children in HighScope programs outscored their non-HighScope peers in initiative, social relations, cognitive development, motor development, and overall development.

Other HighScope Studies

HighScope Foundation has partnered with the federal Head Start in various ways over the years. In the 1970s it led or participated in several studies of Head Start demonstration programs—Home Start and the Developmental Continuity

Project among them. Home Start involved the delivery of Head Start services in participating families' homes. The Developmental Continuity Project brought Head Start programs together with elementary schools. From 1995 to 2004, HighScope was home to one of several Head Start Quality Research Centers. In the first 5 years, the center sought to define and assess quality in Head Start programs; in the second 5 years, it studied the effectiveness of intensive training of Head Start teaching staff in the use of the HighScope Curriculum.

Since 1995, HighScope Foundation has led a longitudinal study of Michigan's Great Start Readiness Program. The study compares 338 children who attended this program as 4-year-olds in 1995–1996 to 258 of their classmates who did not attend, in six selected sites across the state. All of the children came from families whose income was low enough to qualify for program enrollment. Despite the groups being similar on most background characteristics, the group that attended the program was better prepared for school and had higher test scores at fourth grade. A smaller percentage had to repeat a grade, and a larger percentage graduated from high school on time, with the difference more pronounced among children of color.

The IEA Preprimary Project is an unprecedented examination of early care and education programs in 17 countries, coordinated by the HighScope Educational Research Foundation under the auspices of the International Association for the Evaluation of Educational Achievement (IEA). The project has produced a series of reports on parent beliefs, characteristics of early childhood settings, and how these characteristics relate to children's cognitive and language performance at ages 4 and 7. The study found that the world over, mothers spend 8 to 12 hours a day with their 4-year-olds, while fathers spend less than 1 hour. In almost all types of group settings around the world, adults interacting with children use adult-centered teaching strategies more often than child-centered strategies. Yet children in settings in which free, child-initiated activities predominate have significantly better language performance at age 7 than

children from settings in which adult-planned personal and social activities predominate.

HighScope brings and has brought an evaluation mentality to its program planning and development with many program partners, such as the Michigan Department of Education, South Carolina First Steps, United Way for Southeastern Michigan, and Oakland-Livingston Human Services Agency. It has established its Center for Early Education Evaluation to pursue this commitment.

HighScope's enduring commitment is to support programs that ask young people what they want to do and help them develop through their own work and play. Its work is grounded in this vision of human beings as active participants in their own learning and life experiences.

HIGHSCOPE PERRY PRESCHOOL STUDY

The HighScope Perry Preschool Study is the longitudinal experiment conducted by HighScope Educational Research Foundation that identifies the effects of the preschool program run at the Perry Elementary School in the Ypsilanti, Michigan, public schools from 1962 through 1967. The study focuses on 123 African American children born in poverty and at risk of school failure, 58 of whom were assigned to the preschool program. This entry first discusses the Perry Preschool program, the design of the study on its effects, and the study's findings. It then discusses what implications may be drawn from the study about the necessary ingredients for preschool to be successful.

The preschool program provided 3- and 4-year-old children a child development curriculum in

half-day classes and weekly home visits. Compared to non-attendeers, those attending the program had significantly better intellectual and language performance from the end of the first program year through first grade. They had higher achievement test scores during their schooling, particularly at age 14, and a stronger commitment to school. Fewer preschool graduates were identified as educable mentally impaired. Fewer preschool girls repeated a grade, and more of them graduated from high school. As adults, preschool graduates had a higher employment rate and better-paying jobs and were arrested for half as many crimes. The return on investment in this program was at least seven times as great as the investment itself. Several other studies have since found long-term effects and return on investment, fueling a strong advocacy movement and increasing funding for high-quality early childhood programs throughout the world.

Context

Prior to the 1960s, early childhood education was synonymous with nursery school and kindergarten, largely for middle-class children. With the Economic Opportunity Act of 1964 came Head Start, the federally funded preschool program for children of low-income families. The intellectual rationale for this inclusion of a preschool program came from J. McVicker Hunt's introduction of Jean Piaget to the United States and Benjamin Bloom's analysis of the early variability and later stability of children's performance on IQ tests. It also came from the first scientifically studied preschool programs for poor children, by Martin Deutsch in New York, Susan Gray in Tennessee, and David Weikart in Michigan.

In those years, Weikart was special education director of the Ypsilanti public schools. Frustrated at the rampant failure of poor children in the schools without an effective school district response, he joined with Charles Eugene Beatty, Sr., principal of the Perry Elementary School, whose students were African American, to establish the Perry Preschool program. Because some doubted that such a program was suitable for young children, it was evaluated using an experimental design.

Design

The researchers identified study participants at risk of school failure from low-income families living near Perry Elementary School in Ypsilanti, Michigan. Parents' schooling, occupational status, and household density determined families' socioeconomic status. The Stanford-Binet Intelligence Scale measured children's intellectual performance at study entry. The 123 participants in the longitudinal study entered the study in five successive classes at age 3 annually from the fall of 1962 to the fall of 1965 (the oldest class entered at age 4 in the fall of 1962).

These children were assigned to the preschool program group or to the no-program group (who did not attend any preschool program) by objective assignment procedures involving randomization. In each of the five classes, children were ranked into pairs of similar intellectual performance at study entry and randomly assigned to two groups. Some pair members were swapped to equate groups' mean intellectual performance, socioeconomic status, and gender ratios. In younger classes, younger siblings were swapped within pairs to be in the same groups as their older siblings. The children of mothers who were employed and could not participate in home visits were reassigned to the no-program group and pair members swapped into the program group. These procedures resulted in two groups not significantly different on initial intellectual performance; father's presence, schooling, or employment status; or mother's schooling. Because of the switches of children of employed mothers into the no-program group, the program group had significantly more employed mothers than the no-program group (9% vs. 31%). Fortunately for the design, maternal employment at study entry was not correlated more than .13 with any of the major outcome variables.

Program teachers conducted daily 2½-hour classes for children on weekday mornings and made weekly 1½-hour home visits to each mother and child on weekday afternoons, from October through May. Of the 58 children in the program group, the 13 in the first class were in the program for one school year at age 4 and the 45 in subsequent classes

were in the program for two school years at ages 3 and 4. Program staff developed a curriculum model based on the idea that both teachers and children should have a major role in defining and initiating children's learning activities. Now called the HighScope Curriculum, this model is an open framework of educational ideas and practices based on children's development. Adults arrange interest areas in the learning environment; maintain a daily routine in which children plan, carry out, and review their own activities; and join in children's activities, asking appropriate questions that extend their plans and help them think about their activities. They introduce new ideas to children through adult-initiated group activities. They observe, support, and extend the children's play. Using key experiences based on child development theory, they encourage children to engage in activities that contribute to their development.

This study has amassed an unusually rich and comprehensive data set on young African Americans growing up in poverty, with variables representing their status from birth through childhood and adolescence to early adulthood and midlife. The many variables encompass demographic characteristics, test performance throughout childhood and adolescence, school success, crime, socioeconomic success, health, family, and personality development. The planned age 50 study will build on the age 40 study, expanding coverage of health and personality. Attrition in the study sample has been very low and had a negligible effect on analyses of outcomes. Across the 48 measures of 123 cases, a median 7 cases (5.7%) were missing.

The findings presented here are based on comparisons of the program group and no-program group with statistical adjustments to compensate for the effects of participants' gender, Stanford-Binet IQ at study entry, mother's schooling, father's presence and employment status, household rooms per person, and mother's employment status. Reported group differences in outcomes are statistically significant, with a one-tailed probability of chance occurrence of less than .05, using one-tailed probabilities because the study's hypotheses are clearly directional.

Findings

The program group outperformed the no-program group on various intellectual and language tests from their preschool years up to age 7; school achievement tests at 7 to 14; and literacy tests at 19 and 27. The program group had better attitudes toward school than the no-program group as teens. Fewer in the program group were treated for educable mental impairment, and fewer program females repeated a grade. Consequently, more program than no-program females graduated from high school or received a GED, a remarkable 42 percentage-point difference favoring program females.

At 27 and 40, more of the program group than the no-program group were employed and owned their own homes and cars, and the program group had higher median earnings than the no-program group. At 27, fewer of the program group than the no-program group reported receiving social services in the previous 10 years. During their lives, the program group was arrested for half as many crimes as the no-program group; fewer in the program group were arrested five or more times or were ever arrested for violent, property, or drug crimes. Fewer in the program group were sentenced to time in prison or jail.

A causal model suggests the following path from preschool program to reduced crime. Family socioeconomic status impaired study participants' early childhood intellectual performance, but preschool experience improved it, strengthening their elementary school motivation, which reduced the time they were treated for mental impairment. Their improved early childhood intellectual performance and reduced time in treatment for mental impairment improved their literacy when they left high school. Their greater school motivation led them to complete more school. Because they had more school, they had higher adult earnings and committed fewer crimes.

In constant 2014 dollars discounted at 3% (as is standard in multiyear studies), the return to society was \$324,341 per participant on an investment of \$20,093 per participant (\$11,315 per participant per year)—\$16.14 per dollar invested. Of

that return, 76% went to the general public and 24% went to each participant. Eighty-eight percent of the public return came from crime savings, with the rest coming from school and welfare savings and increased taxes due to higher earnings. Almost all of the public return—93%—came from the program effect of reducing crime rates of program males. Over their lifetimes, each male program participant cost the public \$980,431 less in undiscounted 2014 dollars—nearly a million dollars per person.

James Heckman and his colleagues recently reanalyzed the group differences, costs and benefits, and mediators found in the data of this study. While some specific findings differed, the general findings confirmed the study's initial analyses. The group differences reanalysis used innovative statistical procedures to correct for the study's small sample size, departures from random assignment, and multiple hypothesis testing. The cost-benefit reanalysis examined dozens of assumptions and produced hundreds of estimates of return on investment, centering on a benefit-cost ratio of 7.1 to 1, similar to the previous estimate through age 27. The mediator reanalysis, of males and females separately, confirmed the path from preschool to improved intellectual performance to improved school achievement, extending it to reduced use of welfare assistance by females. It found that preschool decreased males' misconduct, thereby reducing their crime as adults and improved females' social relationships and reduced their misconduct, which improved their adult lives in many ways.

Discussion

In the late 1970s, principal investigators of a dozen studies including the Perry study banded together to form the Consortium for Longitudinal Studies. Collaborating in data collection and analysis, the Consortium found robust evidence of preschool program effects on children's intellectual performance at school entry and reduced need for placements in special education and retention in grade. Since then, several other longitudinal studies of early childhood program effects

have joined the Perry study in finding long-term effects and return on investment—the Abecedarian Project, the Chicago Child-Parent Centers Study, and the studies of the Nurse-Family Partnership.

Several more recent studies of state and local preschool programs have found promising short-term effects. But the findings through third grade of the Head Start Impact Study were disappointing. From this body of evidence it can be concluded that model preschool programs and some local and state programs have the program ingredients needed to be highly effective, while the federal Head Start program as a whole does not have these program ingredients to the extent needed to be highly effective. These program ingredients have been identified as fully qualified or well-supervised teachers using a proven curriculum model, engaging parents as partners, and regularly assessing program implementation and children's development. The challenge is to provide such programs to all children in need so they get a fair chance to achieve their potential.

HIGH-STAKES STANDARDS-BASED ACCOUNTABILITY REFORM

High-stakes standards-based accountability reforms are a set of educational policies that define the knowledge and skills children are to acquire (content standards) and the level of proficiency they are to attain on specific standardized measures of academic achievement (performance standards). The high stakes associated with these policies refer to the consequences that are enacted upon children, teachers, schools, school districts, and/or state education systems due to the children and/or a child failing to attain the performance standard. The stakes can range from denying grade promotion to the student, affecting teachers' and/or administrators' salaries and/or tenure, sanctioning or even closing schools or regional education systems, or potentially humiliating education stakeholders by making school-wide or system-wide test results available to the public. Additionally, many states require early educators working in public school settings to be certified by the state, which can necessitate that they attain a particular level of performance on a specified standardized teaching exam—meaning the stake is not being certified by the state.

Many policy makers believe that by defining what children and/or teachers are to know, how

well they are to know it, and tying consequences to these performance expectations they will motivate stakeholders within the education system to work more effectively to ensure all children and/or teachers learn the content standards needed to score well on the mandated exams. This entry first examines the presence of high-stakes standards-based accountability reforms in publicly funded early childhood education (ECE) programs, and then discusses the manifestation of similar high stakes in private ECE programs. It concludes by offering suggestions for best practices in using high stakes as a part of ECE reform.

High-Stakes Standards-Based Accountability Reform in Publicly Funded ECE

High-stakes standards-based accountability reforms emerged in ECE as a result of policy makers implementing these types of policies in elementary and secondary education systems. While high-stakes decisions for students typically do not occur until they are at least age 8, these elementary and secondary policies have been translated into a similar set of reforms for publicly funded early education settings serving children ages 0 to 5. For instance, policy makers have called for the establishment of early learning standards. These content standards, which are typically aligned with the content standards found in elementary school, dictate for ECE teachers and their programs the skills, knowledge, and dispositions children should possess by the time they leave their programs.

These reforms have also led to the implementation of mandated assessment measures for particular early education programs. In some ECE contexts, preschool/prekindergarten children's literacy, mathematics, and/or social skills are tested on a regular basis. There has also been a rise in the use of kindergarten readiness tests given to children as they enter elementary school. Education policy makers and stakeholders can use these assessments in three ways. First, for the children, these test scores might be employed to establish a baseline of what children know and can do and whether they are on trajectory for success on the

high-stakes exams that await them in elementary school. Second, national, regional, or local policy makers may use students' scores to reward, endorse, or sanction the ECE program they attended. Lastly, in some ECE contexts, children's scores may be made available to the public.

The implementation of these high-stakes standards-based accountability reforms in ECE has been tenuous for many within the field. These reforms center on establishing an aligned system of ECE that dictates what children are to know and do at particular points in their schooling, and if they fail to meet those markers, consequences occur. As such, academic achievement within high-stakes standards-based accountability reform in the early childhood years does not necessarily reflect what children have learned or how they have developed since entering a particular early education program. Rather, achieving the defined performance standard simply means that children possess the skills and knowledge policy makers have prioritized in their reforms through their assessment measures. It is unclear whether children learned these skills in their ECE program.

This conception of academic achievement found within high-stakes accountability systems varies from the focus within the field of ECE on helping individual children develop and learn through practices that are in tune with their individual, developmental, and sociocultural needs. Furthermore, for ECE practitioners and their programs, academic achievement is conceptualized as one of the many bands that make up the spectrum of children's development and learning. Thus, evaluating children's cognitive, social, emotional, and physical development and learning is tied to both formative (monitoring student learning) and summative (evaluating student learning) assessments that educators use to monitor their instruction so that they can provide their students with learning experiences that develop the children's individual skills and knowledge in relation to the needs of children and their families, as well as empirically based norms of child development.

Lastly, this shift for the field of publicly funded ECE from one that pivots its instructional decision

making off the individual needs of children within a specific program toward a high-stakes standardized system of early learning that focuses on all children attaining the same level of academic achievement at a particular point in their schooling has been shown to limit the instructional practices of teachers, redefine the purpose of such ECE programs as pre-K, and deemphasize the development of positive interactions between early educators, their programs, and the children and the families they serve.

High Stakes in Private ECE Programs

While private school settings typically do not fall under the purview of most educational reforms, these programs do enact high-stakes decisions upon children and their families through denying them acceptance to a particular type of program (e.g., preschool, kindergarten, or elementary school) or having children repeat an academic year based on a particular assessment measure or application process. Grade-level retention, while not empirically justified, is used both in private and public ECE programs. Nevertheless, denying admission to a program and/or retaining a child based on any type of criteria is a form of high-stakes consequences for the children and families these programs are designed to serve.

Best Practices for High-Stakes Standards-Based Accountability Reform in ECE

While high-stakes standards-based accountability reforms are controversial and their impact on children's learning and development is at best mixed, they remain a part of the field of ECE across the globe. Thus, this entry ends with a brief examination of best practices for high-stakes decisions so that early education stakeholders not only understand how to evaluate the appropriateness of these reforms but can also advocate for policies that support the learning and development of children.

To begin, both research-oriented (e.g., American Educational Research Association) and practitioner-based organizations (e.g., National Association for the Education of Young Children) hold the

position that no high-stakes decisions for children using a single test score should be used until after age 8. Other issues policy makers and early childhood stakeholders should consider when using assessments to make high-stakes or any decision about students and/or educational stakeholders' careers include: what does the test measure (e.g., the content standards), and does this measurement align with the intent of the policy; is the test reliable, meaning does it produce stable and reproducible results; is the test valid, meaning does it measure what it states it measures; and lastly, is the test fair, meaning does it underestimate or overestimate the skills or knowledge of particular linguistic/cultural/socioeconomic groups and can it be used to compare different linguistic/cultural/socioeconomic groups? Ideally, any assessment used in an ECE program should be beneficial for children, be appropriately aligned with their developmental and experiential needs, provide useful information to educators so that they can plan for instruction, offer families insight into children's growth and development, and/or possibly, depending on the assessment, identify children with special needs.

HISTORY OF EARLY CHILDHOOD EDUCATION IN THE UNITED STATES

The origins of the early childhood program movement in the United States can be traced to the religious, philosophical, political, and industrial revolutions that transformed Europe in the 17th and 18th centuries. Some of the influential theorists who have contributed to the field of early childhood include Johann Amos Comenius (1592–1670), a Moravian bishop; John Locke (1632–1704), an English philosopher and physician; Jean-Jacques Rousseau (1712–1778), a German philosopher, writer, and composer; Johann Heinrich Pestalozzi (1746–1827), a Swiss pedagogue and educational reformer; Robert Owen (1771–1858), a Welsh social reformer; Friedrich Wilhelm August Froebel (1782–1852), a German pedagogue and a student of Pestalozzi; John Dewey (1859–1952), an American philosopher, psychologist, and educational reformer; Maria Tecla Artemesia Montessori (1870–1952), an Italian physician and educator; Lev Vygotsky (1896–1934), a Soviet Belarusian psychologist; Jean Piaget (1896–1980), a Swiss developmental psychologist and philosopher; Erik Homburger Erikson (1902–1994), a German-born American developmental psychologist and psychoanalyst; Abraham Harold Maslow (1908–1970), an American psychologist; and Urie Bronfenbrenner (1917–2005), an American developmental psychologist who was born in the Soviet Union.

As a stage in the education and socialization of a child, early childhood typically refers to a child's experiences prior to entering the primary grades at age 6. Early childhood programs and education are complex and varied, with each having a distinct history of its own. This entry discusses the development of nursery, prekindergarten, and kindergarten programs in the United States.

Day Nursery and Nursery School

Day Nursery

Between 1815 and 1860, the United States experienced a flood of immigration with over 5 million new families settling into mostly urban areas. The industrialization and urbanization of the country led women to enter factories. Young children were left to their own devices, wandering in the streets unattended or locked in their homes. Well-meaning, wealthy philanthropic women created service organizations to address what they identified as neglect, vice, and lack of sanitation, by organizing day nurseries to care for the young children of working-class women.

The day nursery in the United States began in Boston in 1828 with the opening of the Boston Infant School, which enrolled children between the ages of 18 months and 4 years of age. The Boston Infant School was modeled after infant schools in Scotland developed by Owen. Those infant schools were established for children 2 to 6 years of age whose mothers worked in factories. In 1854, the Nurses and Children's Hospital in New York City opened to offer child care for infants and toddlers of working women who were patients in the hospital. In 1863 in Philadelphia, a day nursery was opened to care for the children of women working in hospitals and factories during the Civil War. A model day nursery was featured in the 1893 Chicago World Fair, offering care for 10,000 children of visitors to the fair. By 1898, there were enough day nurseries opened throughout the nation to support the creation of a National Federation of Day Nurseries.

Expansion of day nurseries continued in the 20th century, with services being offered in converted homes. These day nurseries were open six days a week, 12 hours a day. They were often oversubscribed and understaffed, with care being provided by matronly women and an assistant, who cared for the children, did laundry, cooking, and cleaning. These places were a last resort for mothers of children who had to work and had nowhere else to send their children.

Many of the day nursery children were the children of immigrants, so emphasis was placed on

teaching children manners and hygiene in the "American way." The virtues of punctuality, obedience, industry, and cleanliness were promoted by training the children to use a napkin, eat in silence, march in a straight line, and giving them tokens for "good" behavior to redeem for articles of clothing. By 1900, kindergarten ideas began to filter into a few day nurseries. Some of the adults in these nurseries attempted to create a curriculum for the children.

Underlying the creation of day nurseries was a deficit model. Mothers were perceived as falling short of the middle-class ideal parent. Very often, they were identified as needing help and their children were accepted into the programs on this basis. Better-funded and organized day nurseries offered working mothers services beyond child care such as classes in sewing, cooking, learning to speak English, job training, and assistance with practical family problems.

In 1933, with approximately 13 million families devastated by the Great Depression, President Franklin D. Roosevelt initiated the Federal Economic Recovery Act and the Works Progress Administration (WPA). Public funds for expansion of child care became available for the first time in history. Ideally, this project aimed to offer jobs to unemployed teachers, nurses, cooks, and janitors. By 1937, over 1,900 day nurseries caring for 40,000 children were in operation throughout the country, mostly housed in schools and following school hours.

The WPA was terminated in 1938, and without funding, day nurseries floundered until World War II. Women were mobilized into war-related work and funds provided under the Lanham Act of 1940 were used beginning in 1943 to support child care for women working in the defense industry. By 1945, over 1.5 million children were enrolled in day nurseries, with more innovation going into the provision of care. The Kaiser Shipbuilding Corporation opened two Child Service Centers where the children of women working in the shipyard were offered a creative program and the mothers were offered shopping and mending services, doctor's appointment services, care for ill children, and take-away dinners at a low cost.

The end of World War II meant that the Lanhams funds, which had been appropriated for the development of day nurseries, were cut in 1946, closing nearly 3,000 nurseries across the nation. From 1950 to 1965, day nurseries were marginalized services, providing facilities for poor families and children with an emphasis on social work and families facing difficulties. In the mid-1960s attitudes toward day nurseries began to shift as more mothers were working outside the home and the federal government supported day care, but mostly for poor families. It was at this time that day nurseries and nursery schools began to merge.

This merger was heralded in January 1964 when President Lyndon B. Johnson declared a “war on poverty” in his State of the Union speech. A comprehensive nursery program called Project Head Start was designed to help break the cycle of poverty, providing preschool children of low-income and rural families with a program to meet their emotional, social, health, nutritional, and psychological needs. In the summers of 1965 and 1966, the Office of Economic Opportunity launched an 8-week Project Head Start.

Nursery School

While day nurseries were designed to provide care for children of poor families, the nursery school was created to provide enrichment for children of affluent families in the United States. The nursery school was intended for children younger than kindergarten age (i.e., 2-, 3- and 4-year-old children). Following World War I, children became a focus in American society, leading to a central concern for the young child’s social, physical, and emotional development. Nursery school educators experimented with pedagogical methods, rather than adhering to one philosophy like many of the Froebelian kindergarten advocates.

The first cooperative nursery school in the United States was created by the wives of faculty at the University of Chicago in 1915 to give them time for Red Cross work while simultaneously providing social education for their children and parent education for themselves. Parent participation and parent fees supported the programs. In 1927, the

Children’s Community Center was organized in Berkeley, California, and is today the oldest continually operating cooperative preschool.

In England, Margaret McMillan (1860–1931), a Christian Socialist, believed young children flourished with the Froebelian emphasis on play and self-activity. McMillan is regarded as the originator of the nursery school concept. Together with her sister Rachel, McMillan began an open-air nursery school in a deprived part of London in 1914. Abigail Eliot (1892–1992), the founder of America’s first nursery school, studied with the McMillan sisters in Deptford, England, in 1921 for 6 months in order to understand the theory and practice of the open-air nursery. She returned to Boston in January 1922 to open the Ruggles Street Day Nursery.

Historically, most U.S. nursery schools were privately funded and often sponsored by and affiliated with universities. They were characterized by their use of child study and psychological theories about children and their families, such as those of Piaget (1896–1980). Unlike those in the United Kingdom that provided services for working-class families, they catered mainly to upper- and middle-class children whose mothers were not undertaking paid labor.

The inclusion of nursery schools in the public education system in the United States was limited by the cost of organizing and running such programs. Further, there was a prevailing view throughout the 20th century that the ideal setting for a young child was at home with the mother. The only exceptions to this were made for the children of the urban poor and in times of national emergency such as the Great Depression and World War II.

In recent decades, public and private provision of preschools has increased dramatically in the United States, as the number of women entering the labor market has steadily grown. At the beginning of the 21st century, nursery school was the general trend and provided a play-based, developmentally appropriate curriculum.

Throughout the 20th century in the United States, privately funded nursery schools adopted play methods more widely than publicly funded

nursery schools, but there were too few of them to meet the demand. Public funding of nursery schools, however, enabled more children to attend, but this has almost always led to their subordination to the demands of the schools for older children.

Prekindergarten

Historically, prekindergarten programs in the United States were supported by private and federal funds. Federally supported prekindergarten programs were established to help poor families, unemployed parents, working parents, and disadvantaged children. Federal funds for prekindergarten programs increased in 1964 when the Equal Opportunities Act (EOA) was passed, the War on Poverty began, and Project Head Start was developed.

Although federal funding of prekindergarten programs increased with the EOA, most prekindergarten programs were operated by private agencies. These private prekindergarten programs, established in 1922, were mainly for Caucasian children from high-income families whose mothers were not in the workforce. Private programs provided educational enrichment and socialization for children, not to support working mothers.

Staffing has, historically, been a challenge for public prekindergarten programs. Many teachers in private programs lacked the early childhood training required of public school teachers. The majority of prekindergarten teachers in private programs were considered to be child care providers rather than educators. Despite this, children who attend prekindergarten programs are more likely to have a successful transition into primary grades and better academic attainment than those children who do not attend prekindergarten. With the advent of the Child Development Associate (CDA) credential for paraprofessionals and state licensure that includes prekindergarten, the quality of preparation has been enhanced.

The United States also has begun putting systems into place to improve preparation of pre-school teachers. Support for the professional development of the prekindergarten workforce now includes increasing availability of infant/

toddler coursework and training. This is leading to formally recognizing professional achievement through award of an infant/toddler credential, certificate, certification, or endorsement.

Kindergarten

The kindergarten movement was not designed as a compensatory program to address the needs of children living in poverty. Parents paid for their children to attend private kindergarten education because it was viewed as a “positive good.” Froebelianism began in the United States as a German cultural movement. The first kindergartens were established by women who had studied with Froebel or one of Froebel’s students. The kindergarten was designed to preserve the German language and culture for second-generation German Americans. The first kindergarten in the United States was established by a student of Froebel, Margarethe Meyer Schurz, in 1856 in Watertown, Wisconsin. There are records of nine or 10 other German-speaking kindergartens from the 1850s to the early 1870s in Ohio, Kentucky, New York, Michigan, and Wisconsin.

Elizabeth Peabody and Susan Blow promoted national acceptance of the kindergarten. Peabody opened the first English-speaking kindergarten in the United States in Boston in 1860. The kindergarten classroom differed greatly from the primary school setting, with movable tables and chairs and children encouraged to play and spend time learning outdoors. Materials were arranged for the child to have access to everything in the setting at child scale.

Blow, with the support of William Torrey Harris, began the first public kindergarten in St. Louis, Missouri, during the 1872–1873 school year. Blow had studied kindergarten methods with Maria Kraus-Boelte, a pioneer of Froebel education in the United States. One challenge that Blow and Harris faced was cost—kindergarten cost \$4 more per child than primary grades. To compensate, Blow established two sessions of kindergarten per day—one morning and one afternoon. Children between the ages of 3 and 5 years were enrolled in the St. Louis kindergarten, allowing young children a

transition period between early childhood education and the rigid and formal primary grades education. In 1883, the Missouri Supreme Court upheld complaints about the St. Louis public schools funding kindergarten for children under the age of 6. Schools were forced to change the elementary school entrance age to 5 and charged families of children age 5 a fee to attend kindergarten. Blow withdrew from active kindergarten work in 1884.

In spite of these challenges, the popularization of kindergarten continued. During the 1880s and 1890s, kindergarten was exhibited at fairs and expositions across the nation. Increased awareness in the southern United States was a result of a model kindergarten at the New Orleans Exposition in 1885. The Columbian Exposition in Chicago in 1893, where private, charity, and public kindergartens from around the country were displayed and held conferences, produced an unparalleled interest in the movement.

Tuition for kindergarten was high compared to fees for the day nurseries, resulting in kindergarten programs being geared to children of well-to-do families. However, in 1870, the Boston, Massachusetts, school board opened a tuition-free, experimental kindergarten for children between 4 and 6 years of age. A second, tuition-free public kindergarten opened in Brighton, Massachusetts, in 1873.

By 1880, 400 kindergartens had been established in 30 states. Although advocates of kindergartens were divided on the issue of whether preparation for the academic work of first grade should be stressed or whether an emphasis should be placed on the moral, emotional, physical, and social development of children, kindergartens had become a major force in American education by 1900 when over half of all kindergartens in the United States were housed in public school systems.

By the 1900s, the kindergarten movement had become very progressive. Free kindergartens were popular and kindergarten was seen as a community center for the neighborhood. In 1903, the Committee of Fifteen was established to solve the debate over keeping the Froebelian principles of

kindergarten or changing to scientific principles. The name of the group was soon changed to the Committee of Nineteen because the original 15 members could not come up with a solution.

Blow continued to fight for Froebel's principles while a newcomer, Patty Smith Hill, felt that Froebelian rules were too rigid and should give way to new ideas and principles. Hill felt that a child's interests should correspond with significant educational experiences. She began to develop new songs, toys, and activities for the new American kindergarten. Teaching double sessions became common practice, making it difficult to interact with parents and families as was common practice in the past. By the 1920s, kindergarten programs were firmly entrenched in the public school system, increasingly looking upward toward the primary grades and preparation for formal schooling, rather than focusing on the unfolding development of the young child. Unification between the kindergarten and first-grade programs evolved, leading to the first-grade curriculum moving down into the kindergarten. The age range of the kindergarten was also changed from admission of 3- to 7-year-olds and limited to 4- to 5-year-olds.

The launching of Sputnik by the Russians in 1957 brought forth complaints about the U.S. education system, leading to further pushing down of the first-grade academic skills to the kindergarten curriculum to prepare children for later academic success. In the 1960s, the nation noted the devastating academic failure of children of the uneducated and poor, leading to a movement to close the gap between the students of high and low socioeconomic backgrounds and to build more kindergartens in low socioeconomic areas. Educators felt that a new rationale and methodology in the kindergarten curriculum would close this gap. The nation embraced the ideal that early education was the remedy for American poverty. Research conducted in the 1960s led to results that confirmed kindergarten experiences correlate to academic success in later years.

By the 1980s, enrollment of all 5-year-olds had risen to 96%, and every state had public kindergartens, with mandatory enrollment in 12 states and the District of Columbia. (As of 2014,

kindergarten was mandatory in 15 states and the District of Columbia, according to the Education Commission of the States.) The kindergarten curriculum either focused on total learning and growing or became a watered-down version of first grade. School readiness became an issue with the 1994 passage of the Goals 2000: Educate America Act, leading to some parents keeping their children from entering kindergarten until they reached 6 years of age, rather than enrolling them at the expected age of 5 years old, to ensure their future academic success as some of the oldest children in the class.

Early childhood education and programs have a complex and rich history in the United States. Debates continue that ensued over 100 years ago—appropriate age for a child to begin kindergarten, whether a child should attend an early childhood education program or stay at home, funding and resourcing for early childhood programs—to name a few. Having a historical perspective of where nursery, prekindergarten, and kindergarten education began, and the theory behind these programs, will allow for informed decisions about the future of programs for young children.

HISTORY OF EARLY CHILDHOOD EDUCATION POLICY

Early care and education (ECE) programs in the United States comprise center-based child care, family child care, preschools, and kindergarten programs. According to the National Institute of Child Health and Human Development, ECE programs differ by quantity and quality. A review of the history of ECE programs and policy in the United States reveals that much of child care was established in the United States as a substitute to maternal care when mothers were not available to care for their children (due to work) or when they were deemed “inadequate” (as in culture of poverty policies for poor families). However, ECE support for families has been and continues to be undervalued and inadequate (in terms of quality and scope).

The 1800s

In the early 1800s, early childhood care policies provided child care support for women who went

to work in the factories. These “day nurseries” proliferated due to the need to keep children out of the streets. The first day nurseries in the United States were designed after French day nurseries, *Crèche*, and they only supervised children and provided basic care.

By the late 1800s and early 1900s, day nurseries provided care that was protective, custodial, and physical in nature. However, only a small percentage of working mothers used these day nurseries. Boston Infant School was established in 1828 and the Nursery for the Children of Poor Women opened in the city of New York in 1852. During the Civil War, women were needed at the factories and at hospitals. Therefore, in 1863 the first permanent day nursery opened in Philadelphia, Pennsylvania, to care for children of Civil War workers. Day nurseries were designed to keep children out of orphanages. Most of the day nurseries around this time were subsidized by charitable organizations. By the end of the 19th century, ECE was primarily custodial—and mainly for poor mothers, immigrants, and minorities in need of charitable care.

The Progressive Era

Toward the latter half of the 19th century, early childhood programs experienced a transformation and an increase in professionalization. The kindergarten, based on the theories and practices of Friedrich Froebel in Germany, came to the United States. Froebel invented kindergarten, and he developed an educational philosophy grounded in four principles: creativity, social participation, free self-expression, and motor expression. He also acknowledged that education begins in infancy and viewed mothers as ideal teachers; thus, his educational programs were run by female teachers. After the German Revolution in 1848, many Germans immigrated to the United States. Among them were female educators trained in Froebel’s kindergarten educational system. These female educators are credited for bringing the kindergarten to the United States. Educationalists such as Caroline L. Frankenberg and Margarethe Schurz opened private and independent kindergartens in the United States, but it was Schurz who established

the first kindergarten program in Wisconsin for German immigrants, in 1836.

Froebel’s educational methods underscored kindergarten curricula during the last half of the 19th century. By 1914, every main city in the United States had public kindergarten programs. Froebel’s theory and educational methods motivated and influenced the work of prominent educators, such as Maria Montessori and Rudolf Steiner. By the early 1900s, Froebel’s educational philosophy was widely accepted in most kindergartens in the United States.

Despite the popularity of Froebel’s philosophy, progressive educators questioned Froebel’s methods due to the rigid implementation of them at the time (which left little room for individual creativity). A leading critic was Patty Smith Hill, one of the main leaders in the kindergarten movement. She challenged the practice of a strict adherence to Froebel’s methods. She studied other leading educators such as John Dewey and Francis Walker. Her work created the foundations for the modern kindergarten programs in the United States. Patty Smith Hill and John Dewey contributed to the field of education by extending kindergarten programs to the West Coast of the United States.

In addition to the kindergarten movement, by the early 1900s, day nurseries became “nursery schools” and shifted from purely babysitting to promoting cognitive and social development in children under the age of kindergarten entry. As kindergarten programs extended throughout the United States, nursery schools built momentum across the country. Many of these ECE programs lacked quality and, according to Sonya Michel, some progressives argued that placing children in programs where they received inattentive and substandard care, while their mothers sought low-wage and physically arduous jobs, was neither an improvement nor a goal for society. Therefore, a counter to ECE programs was a maternal pension that would allow mothers to stay home and care for their children. This gained widespread popularity and by the 1930s most states had some form of a mother’s pension for poor mothers. According to Michel, the mother’s pension achieved greater success than the ECE movement due to the fact that it

supported rather than challenged conventional gender roles.

The Mid-20th Century

Due to federal and state funding cuts in the 1930s during the Great Depression, kindergarten programs went from being full-day to half-day programs. During both the Great Depression and World War II, only a handful of full-day kindergarten programs were still in service. From the 1930s to the 1950s little changed with kindergarten programs.

Due to World War II and the absence of able-bodied men for the factories, women took the men's place in the workforce. This created a need for more nursery schools and child care centers. The United States government allocated \$6 million in 1942 to support working mothers with young children. Children of women in the workforce were eligible for child care, and many states supplemented this federal aid. In 1946, after World War II ended, many women were forced to return to their homes, and the federal government stopped funding child care programs in most states. Only California, New York City, and Philadelphia continued to utilize public funding for child care programs. Due to public outcry, President Truman allocated \$7 million to continue the child care program through 1946.

There was a lack of consistent public funding for nursery schools or day care centers until the mid-1960s. Between 1948 and 1966 the percentage of married women with children in the workforce increased from 10.8% to 24.2%. The child care programs that remained opened provided care for those married women who remained in the workforce. In 1962, President John F. Kennedy signed a bill approving federal funding for child care programs. Then in 1967, the Work Incentive Program extended federal funding for child care to low-income families in jobs or job-training programs. In 1969 the Federal Office of Child Development was established in the United States. In the mid-1970s, indirect benefits such as income-tax reductions for child care and deductions for welfare mothers became popular again. ECE was, by

this time, bifurcated by class and race, with middle-class, predominantly white families experiencing predominantly private child care while poor families of color were in subsidized or informal forms of child care.

Subsidized Child Care and Welfare Reform

Although the first prekindergarten (pre-K) programs were established in 1922, only three states provided prekindergarten programs before 1960. Pre-K intends to prepare young children for kindergarten and lay the foundation for continued success through third grade. All pre-K programs share three goals: (1) high standards, (2) school readiness, and (3) serve 3-year-old children or a combination of 3- and 4-year-old children. Studies find that the majority of ECE programs for young children in the United States suffer from low to mediocre quality, high staff turnover due to low wages, and too few spaces for too many young children in need of early childhood education.

One of the longest-running pre-K programs is Head Start, which was created during the War on Poverty in January 1964 under President Lyndon Johnson. In 1965, President Johnson initiated the project Head Start and utilized the Office of Economic Opportunity (OEO) to launch this program. Head Start began as an 8-week summer program under the supervision of nursery school teacher Jule Meyer Sugarman. The goal of the program at its inception and still today is to get children in poverty ready for elementary school. The Office of Head Start reported in 2010 that it serves about 900,000 low-income children and their families. In 1994, the reauthorization of Head Start developed a new initiative to extend Head Start to infants, toddlers, and pregnant women and their families (Early Head Start). In the 1980s, ECE programs took a hit in funding due to cuts to federal spending for child care support for low-income families. During this time, private child care programs proliferated but the majority of these programs were out of reach for low-income families. However, the Child Care and Development Block Grant of 1990, which distributed \$825 million to states,

provided some support for low-income families during this time.

The division in ECE between the middle- to upper-income versus low-income families widened during the Reagan era, and this division was exacerbated by welfare reform initiatives during the Clinton era in the 1990s. Welfare reform programs created stringent work requirements on welfare recipients, many of whom were mothers with young children. Due to the realization that requiring mothers to work will also require child care support, Congress created the Child Care and Development Fund, which replaced the Child Care and Development Block Grant from 1990.

ECE Today

Many educators, policy makers, and parents advocate for universal preschool. In 2013, President Barack Obama announced a proposal to provide high-quality preschool for every American child. In December 2014, President Obama announced an investment of over \$1 billion for the early education and development of American children. The 2016 federal budget includes \$750 million to help states create and expand high-quality preschool programs in low-income communities. Furthermore, strides are being made to improve quality in, primarily, center-based care through quality rating and improvement systems that many states have adopted. As of 2015, with the exception of one state, states are implementing or in the planning stages of putting systems in place to improve child care quality.

Young children continue to be in less formal forms of ECE than the center-based forms of care. This is particularly the case for very young children from low-income and ethnic minority families. Informal care accounts for a substantial percentage of child care (estimates range from one-third to one-half of children under 5 years of age) but it is less studied and much is unknown about the experiences of children in these less formal forms of ECE. Therefore, policies that target center-based care will not cover the majority of children in child care.

There continues to be variation in regard to quality, availability, and spending. All forms of

child care struggle with maintaining or achieving high quality given the rates of staff turnover (due to low wages and low regard for the work) and rising costs of care. The United States lags behind other industrialized countries in its support for quality ECE for all families. In countries such as France and Denmark, ECE is free and considered a necessity for the full functioning of society. ECE in the United States has experienced significant developments since the 1800s and challenges remain before all families, rich or poor, of any ethnicity or language, can assume that quality, nonparental care will be available and affordable.

HOME VISITATION WITH MOTHERS AND INFANTS AND CHILDREN

For about half a century, home visitation has been an essential ingredient of programs for low-income, low-education families with the primary goals of enhancing the quality of mother-child relationships and supporting enriched mother-child language and learning interactions.

History and Goals of Home Visitation Programs

Among the earliest programs was the Appalachia Educational Laboratory program HOPE (Home-Oriented Preschool Education). Of the 36 Parent and Child Centers funded in 1967, some models were home based rather than center based, or they were a combination of both. For the Houston Model, for example, providers weekly visited low-income Mexican American mothers for about 1½ hours. The goals were to enhance parental knowledge of their important role as teachers of their infants and young children, and to strengthen the family through parent involvement. This outreach was particularly culturally urgent, since initially some fathers would not permit mothers to participate in any program outside of the home.

In Florida, Ira J. Gordon pioneered an early outreach program for mothers of infants. He produced many easy-to-read how-to descriptions of home visitation interactions and activities. Adapting Gordon's Follow-Through model, Project Home Base provided paraprofessional home visitors for about 300 families in Yakima. In Tennessee, Susan Gray pioneered a summer home visitation program to ensure that low-income young children would not lose learning gains made during their year at the center.

Parents with children with developmental difficulties may have transportation issues. The Portage Project was created to serve parents and handicapped preschoolers aged 0 to 6 years, where a professional educator provides materials so that parents can tutor their children at home.

Head Start has included home visitation programs since 1972. In 1973, the Child and Family Resource Program (CFRP), as part of Head Start, coordinated comprehensive services for families with children from birth through 8 years. Families could choose from a variety of resources and delivery systems, including home visitation. CFRP programs provided a range of resources, such as prenatal and preventive health care, family planning supports, and dental services, as well as supports for child transitions from Head Start to elementary grades.

In Long Island, New York, Phyllis Levenstein pioneered the Home-Child program. Home visitors over a 2-year period bring low-income moms a new book or toy every 2 weeks to help their young children increase verbal skills through book sharing and toy play activities. Rapport is established early on as the mother and home visitor jointly assemble a case to hold the materials provided. This program continues to provide services to prevent later school disadvantage.

In California, Rose Bromwich distilled the findings from her program with young mothers to provide detailed scripts of the lessons mothers were to carry out with their little ones. Her book also provides detailed examination of reasons for successes or failures with families.

J. Ronald Lally and colleagues in Syracuse, New York, provided an omnibus program for infants and children for families with low-income, high school drop-out, single mothers. Home visitation began during the second trimester of pregnancy and continued until the child graduated from the Family Development Research Program (FDRP) at 5 years of age. Paraprofessionals taught the teen mothers learning games, offered a toy and book lending library, and provided nutrition information. They modeled activities and encouraged mothers to interact in positive ways as teachers of their infants and young children. The Children's Center provided quality care for children from 6 months of age so that mothers could continue their education or seek job training. Mothers were often encouraged to come to group meetings at pick-up time when potluck suppers were provided as well as an opportunity to see their children's projects. Sensitivity to maternal needs was fundamental. One home visitor rang the doorbell on a blustery winter day and asked the mom for some newspapers to leave her wet boots outside the door so that she "would not mess the apartment." This mother lived in a chaotic situation with wet diapers strewn on couch and chairs. Over the next weeks, the visitor found cleared spaces for her to sit down. Respect and consideration for the parent is a primary value for home visitors. When the FDRP children were in their teens, follow-up comparisons with carefully matched controls showed far

fewer convictions for juvenile delinquency and less recidivism in youth who had been enrolled more than a decade earlier. Female, but not male, youth had better school records. Parents reported FDRP youth were more sociable and caring.

Home Visitation: A Primary Mental Health Support System

Selma Fraiberg pioneered what she called “kitchen therapy”—frequent home visitations over a lengthy period of time, with families where a baby was in grave emotional danger. One depressed and emotionally detached mother wanted to give her baby up for adoption. Another was starving her baby who was in severe medical danger from failure to thrive. This mother hated feeding her baby; after he fed himself a bottle, she held him over the sink (rather than putting him to her shoulder for a burp), where he then vomited. In these cases, with such serious developmental implications, the therapist was a highly trained social worker. She empathized frequently and made an alliance with each mother, to help that mom feel the emotions (often full of rage, hatred, sadness, and bitterness) from her own early childhood suffering of rejection, beatings, neglect, and even incest. The home visitor then must provide the mother with a deep sense of feeling loved and protected. The mother is carefully nurtured and helped to express emotionally as well as remember verbally the anguish of abuse suffered and thus find a way not to inflict her past upon her child. These mothers often had pathological identification with aggressive behaviors, such as severe neglect and brutal paddle beatings that they had received in childhood. The home visitor needs specialized skills to help such families rid the nursery of malignant “ghosts” from the past.

Evidence for this need for specialized skills can be seen in the outcomes of home visitation programs that focus on families with particular issues, such as drug abuse. The National Center on Child Abuse and Neglect conducted a randomized trial of biweekly visits with single, high school drop-out women who were drug abusers. However, a few years later, developmental scores of the children

were not higher than controls. One Birth-to-Three project employed paraprofessionals to visit families with chemical dependency. At the end of program many mothers still had abusive partners, and there was a high rate of birth defects in the infants born. Thus, a more intensive intervention model may be required for families with more urgent needs.

Timing of Home Visitation and Training for Home Visitors

When should home visiting begin and how long should it last? Visitations scheduled too many weeks apart may not meet the needs of families in crisis. Timing of initiating home visitation for families varies. Some programs only provide visits when a preschooler enters the program. Yet, with vulnerable parents, timing may be crucial. Research by Alice Sterling Honig and Christine Morin indicates that starting home visits prior to the birth of an infant in a high-risk family serves as a strong preventive measure in decreasing confirmed cases of abuse/neglect several years later in comparison with at-risk moms where home visitation started months after the baby’s birth.

If a mother has just experienced an episode of violence with a partner, the home visitor may have to attend empathically to the mother’s needs before introducing any new activity. If there are other children in the home, sometimes a second visitor is needed to attend to the other children while one visitor focuses on the mother and baby, suggests Bromwich. If the mother seems weary and overwhelmed, one of the dozens of jobs the home visitor might be carrying out is to help wash and dry dishes piled up in the sink. Honig, in *Parent Involvement in Early Childhood Education*, provides dozens of such tasks and activities that may be required (in addition to helping a parent make homemade toys from egg cartons and empty toilet paper rolls, for example), in the course of a visitor’s multifaceted work with families. Visitors can provide brief, easy-to-read activities for parents and children (such as those in Honig’s *Playtime Learning Games for Young Children*), particularly important for low-literacy parents or immigrant parents just learning English.

The FDRP provided intensive initial 2-week training and then weekly follow-up training for paraprofessionals, who were familiar with the culture of the families served. Weekly reports were required on how well moms had carried out an activity with baby. The paraprofessionals, a cadre of child development trainers, learned child development milestones and practiced role-plays, including positive encouragement skills to use while teaching mothers various games. Flexibility, patience, and genuine warmth are central personality characteristics home visitors need. Ingenuity helps also. Once, an FDRP visitor was not admitted to the apartment and yet heard mom and boyfriend laughing behind the door. With permission, she phoned from a neighbor's apartment. When the mom acknowledged remembering she had made the appointment, the visitor cheerfully remarked, "Well, I am just next door; so thank you for opening your door and I will be right there for you!" Debriefing sessions are important for home visitors. They need to share frustrations and puzzles, as well as creative techniques and ideas with others in their cadre.

Home Visitation as a Deterrent to Insecure Infant Attachment

Dymphna van den Boom reported on a study of low-income Dutch mothers of babies with highly irritable temperaments who were randomly assigned to receive home visitation or not. Mothers in the experimental group were taught how to swaddle and to soothe their highly irritable infants. These interventions worked. Visited infants at 1 year were impressively far more likely to be securely attached to mother (as measured by the Ainsworth Strange Situation) than the babies who had not received home visitation.

Formative and Summative Evaluation Measures

Measures of program success or disappointment vary. Mothers' own remarks are often a yardstick of the degree of trust built with a home visitor. Trust is the foundation that can support maternal

changes toward more involved, pleasurable, and facilitative mothering transactions with a very young child. One FDRP mother confided that she had not believed a visitor "was in it for anything except the money" and now felt that her home visitor really cared about her and her child. Some parents begin to use more positive discipline techniques and cut down on whippings. One mother learned from the home visitor how to make a one-dish casserole and could then sit with her children at dinner in contrast to the mealtime chaos she had reported initially. Bettye M. Caldwell and Robert H. Bradley's Home Observation for Measurement of the Environment (HOME) checklist has proven useful in monitoring positive provision or worrisome lack of progress in parenting transactions that the visitor is encouraging. Some programs use standardized intelligence and language scales to learn whether the child is still lagging or on target in language, learning, or motor milestones.

Sleeper effects of programs may occur years after children have moved to elementary schools or even later. David P. Weikart, founder of the Ypsilanti Carnegie Infant-Education Project, revealed such effects when program children were in early school grades; this program also provides curricular guidelines for home visitors, according to Dolores Z. Lambie and colleagues.

In a randomized control group trial in Elmira, New York, David L. Olds recruited trained nurses to make home visits beginning prenatally. The Nurse-Family Partnership program reported 19 years later fewer repeat pregnancies, fewer childhood injuries, and less cigarette smoking among the home-visited moms, as reported by John Eckenrode and colleagues. This program has been replicated nationwide.

Home Visitation Can Be Challenging

What accounts for lack of success in home visitation work? Some mothers have suffered abandonment and are very slow to warm up lest if they show their anger at the "stranger" who visits, then the visitor might stop coming. A home visitor has

to be able to reassure a mom that despite her anger, the visitor will be there for the mom week after week.

A home visitor needs to engage the parent in the delights of baby, watching for tiny signs of learning and developing. A home visitor has to be alert to tiny positive changes in the mother–child relationship and clearly, with loving admiration, point out how much the child needs and loves to have a mom who can tell when the child needs intimate attention, food, or a diaper change. The visitor helps parents empathize with what the child is feeling (e.g., after many changes of babysitters) rather than calling a cranky, crying tot a “mean kid.”

Some families have too many problems, especially when the mother experienced severe childhood abuse, no current socially supportive partner or family member, and depression—so it seems too difficult to focus on the needs of the infant. Specialists are needed for such cases.

Optimism should be part of a home visitor’s emotional toolbox. Sometimes peaceful modeling causes a sudden change. One mother reported contemptuously and angrily that her toddler tore books and she would not allow him near a book. When the home visitor demonstrated snuggling with the toddler, while turning the pages slowly and exclaiming over each monkey (rather than reading the *Curious George* story as written) the mother was so amazed at the toddler’s attention and interest that she consented to go with her home visitor to get a library card and take out books to share with her child. A home visitor rejoices in small changes.

The Value of Home Visitation

With persistence, skills, knowledge, patience, and a vast reservoir of genuine caring for the families served, home visitors make a positive difference daily in the lives of stressed families and those who need supports to understand and meet the emotional and cognitive needs of young children for intimate, language-rich, and wisely programmed learning experiences that parents can be so special in providing during everyday interactions. The May 2015 National Summit conference

on Quality in Home Visiting Programs attests to the continuing vibrancy and importance of this delivery system for services to families and young children.

HOME VISITS

Home visits are a form of service provision where early childhood professionals work with children, parents, and families in the context of their own home environment. Home visits are often used as part of early childhood programs to enable teachers to learn more about children in their care and to promote parent involvement. During the past 50 years, as a part of the War on Poverty in the 1960s, there has been a growth in the use of home visits as an intervention strategy to promote the adaptation of young at-risk children and their families. Renewed interest in home visits has occurred since 2010, when the U.S. Congress instituted the Maternal, Infant, and Early Childhood Home Visiting (MIECHV) Program. Authorized by the Affordable Care Act, this program provides federal funding to expand home visiting services to families from pregnancy until children turn age 5. This entry provides information on different models of home visits, and service considerations in implementing home visiting programs.

Models for Home Visits

A Component of Center-Based Programs

Home visits are a part of many center-based early care programs and are offered by early childhood teachers and educational professionals. Visits may occur prior to the start of the school year and at other times during the school year as a means for teachers to get to know the child and family. When used at the start of the year, home visits may help the child transition to the school environment and adjust to a new school, classroom, or teacher.

There are multiple reasons why early childhood professionals may find home visits valuable. Visits can help teaching staff better understand the ecological context of the child and family. They can also become more familiar with family culture and parenting practices within the home in order to better meet the child's needs in the classroom. Meeting with parents and families may help increase communication, facilitate home-school connections, and build relationships between parents, teachers, and children to facilitate parent involvement. Home visits may also be used to link parents and families with other educational, social, health, and community services they need to support their child developmentally, academically, and socially.

Intervention Programs

Home visits can also be offered as part of preventive programs or as an intervention strategy to assist at-risk children and families. Programs may be stand-alone efforts or integrated as part of a larger early childhood program or intervention. In the United States, there are home visiting components to educational programs such as Even Start, Early Head Start, and Head Start. Among the home visiting models in use are interventions such as the Nurse-Family Partnership, Parents as Teachers (PAT), Healthy Families America, the Parent-Child Home Program (PCHP), and Home Instruction for Parents of Preschool Youngsters (HIPPIY). These models have different goals, target populations, and service models.

A common characteristic of programs is that visits are offered at regular intervals to families

within the home environment by educators, health care personnel such as nurses, social workers, or other human service workers. While home visits may be conducted by early childhood professionals, some models of home visiting utilize paraprofessionals trained in the application of the particular model, or parents who have successfully completed home visiting programs. Service intensity and duration of programs can vary greatly depending on the model. Visits may occur anywhere from biweekly to monthly. Some programs require families to participate for a specific duration of time or receive a certain number of visits to complete the program curriculum; others may only serve families until children reach a specified age.

Programs have a wide range of goals including promoting children's health, well-being, and improving educational, cognitive, and developmental outcomes. They can also support parenting to decrease parental stress, increase knowledge of child development, support parental use of age-appropriate childrearing and discipline strategies, improve parent-child relationships, and ultimately prevent child maltreatment. Programs may also assist with family development including supporting family adaptation across a transition (e.g., becoming a new parent), fostering self-sufficiency, family cohesion, communication strategies, and managing family challenges including mental health issues, trauma, and social isolation.

Programs may serve children and families at different stages, from pregnancy through the early childhood years. Programs may target different groups of families for intervention including those living in poverty, teen parents, children with health risks or developmental disabilities, immigrant families, Native Americans living on reservations, parents with mental health concerns, and caregivers with limited educational attainment.

Service Considerations

Home visits are utilized to reduce families' barriers to accessing services. However, program retention can be a problem for all family support

programs, including those that are home based. Early childhood professionals working within the home environment need to be cognizant and respectful of family diversity, cultural norms, and practices, and be attentive to family needs and strengths to empower families. In implementing programs, staff must be trained to help them learn how to build strong relationships with caregivers and to fully understand how to best implement the program model being utilized. Both the quality of the home visitor-family relationship and service intensity are important to family retention and progress in programs.

While research on specific models shows the promise of home visiting, attention to program accountability, implementation, quality, and effectiveness, both short- and long-term, is needed. The Maternal, Infant, and Early Childhood Home Visiting Program has provisions to increase our knowledge base regarding home visiting programs through the use of rigorous, experimental-design evaluation studies of funded interventions.

HOME-BASED EARLY CHILDHOOD EDUCATION

Home-based early childhood education refers to the array of early care and education (ECE) arrangements provided for children under the age of 5 in home-based settings. These arrangements can be categorized as relative care (care by a relative of the child, such as a parent or grandparent, in either the child's home or the relative's home), nonrelative care (care by a nonrelative, such as a babysitter or nanny, typically in the child's home), and family child care (care of a small group of children in the provider's home). This entry examines patterns of use of home-based ECE settings, the quality of these settings, and links between participation in these settings and children's development. The concluding section discusses implications for policy and practice.

Patterns of Use

The majority of children under age 5 in the United States today regularly spend time in ECE arrangements. A substantial share of these children are cared for in home-based arrangements. According to U.S. Census data, in 2011, 42% of children under 5 were cared for by a relative and 11% were cared for by a nonrelative, in either the child's home or the provider's home. Twenty-four percent of preschoolers were regularly cared for by their grandparent and 18% were cared for by

their father. Less common was care by other relatives (7%), by the mother while she worked (4%), and by siblings (3%).

There is variation in the use of home-based ECE arrangements by race/ethnicity, family income, and child age. The evidence for race/ethnicity is mixed. Some national studies suggest that the use of home-based care is highest among Hispanic and Black families, but other national surveys have not found such variation. Regardless, across non-Hispanic White, Black, Hispanic, and Asian families with employed mothers, fathers and grandparents are the most common child care providers. With regard to family income and poverty status, children from higher-income families are more likely to be cared for in center-based settings and children from lower-income families are more likely to be cared for in home-based settings. According to U.S. Census data, families with employed mothers living below the poverty level are more likely to rely on sibling care (21%) than those living at or above the poverty level (9%). In contrast, those living at or above the poverty level are more likely to rely on family child care (8%) than those living in poverty (4%). There is also variation in the use of home-based care by children's age. Children under age 3 years are most likely to have a home-based arrangement as their primary source of non-parental care, whereas preschoolers (3- and 4-year-olds) are most likely to have multiple care arrangements that include some home-based care.

Quality of Home-Based Arrangements

The quality of ECE settings is typically defined in terms of *process* and *structural* features of care. *Process* refers to the nature of the caregiver-child relationship and the interactions within the ECE setting. Across home- and center-based settings, children show better developmental outcomes when their caregivers provide plenty of verbal and cognitive stimulation; are sensitive, responsive, and supportive; and give children large amounts of attention. *Structural* features of care include the caregiver's educational background and training, the total number of children cared for in the ECE setting, and the ratio of children to caregivers.

Each of these features has been linked to process quality and, in turn, to children's development. Across different types of care, centers tend to have the largest group sizes, the highest child–adult ratios, the most stimulating physical environments, and caregivers with the most training and education. Family child care homes tend to fall in between centers and the care provided by grandparents and nannies on these dimensions of quality.

Effects of Home-Based Settings on Children's Development

Across center- and home-based settings, children with more educated and trained caregivers and those who receive higher-quality care tend to score higher on tests of cognitive and language development. Consistent with the stronger educational focus of center-based care, children in centers have been found to score higher on standardized cognitive assessments than children in home-based settings. With regard to children's social-emotional development, however, there is evidence that more time spent in center-based care and with large groups of peers in early childhood is related to children's behavior problems, suggesting that there may be social-emotional benefits of home-based care. The evidence for type of care is more mixed for children from low-income families. Some research suggests that low-income children benefit cognitively from center-based care and that those in family child care homes show higher levels of behavior problems than those in other home-based settings. Other evidence, however, suggests that it is the quality of care—not the type of care—that matters most for low-income children's development.

Implications for Policy and Practice

Across demographic groups, home-based ECE arrangements are widely used by parents of young children. Research suggests that the quality of home-based care is better and children are better off when caregivers are well educated and trained

and when group sizes meet recommended cut-offs. Although informal home-based arrangements such as relative care are not regulated by the state, family child care homes are subject to state regulations. These regulations vary widely. The evidence presented here suggests that, in order to support young children's optimal development, states should regulate the education and training of family child care providers and require that child care homes meet recommended group sizes.

HOME-BASED EARLY INTERVENTION PRACTICES

Home-based early intervention (HBEI) practices refer to methods and considerations for providing

early intervention (EI) services to children and families affected by or at risk for disabilities in naturalistic and inclusive settings. EI services delivered in the home are often misunderstood and likened to “babysitting.” This entry (a) describes HBEI practices, (b) delineates benefits to HBEI practices, and (c) discusses ethical considerations specific to working in a family’s home.

Overview

Recent changes in practice and policy recognize naturalistic settings as the most beneficial and appropriate place to provide EI services. A naturalistic setting is considered any place where the child engages in everyday activities (e.g., home, backyard, local library). Consequently, early interventionists’ approach to service provision has experienced a paradigm shift requiring profound changes in the preparation of service providers. Traditionally, EI was provided in clinical or classroom-like settings and was considered to utilize a child-centered approach. Providing services in the home or naturalistic settings requires service providers to use a family-centered approach. In a family-centered approach, the service provider is considering the entire family system (i.e., all of the family members) when programming and delivering EI services.

Federal special education policy, the Individuals with Disabilities Education Improvement Act of 2004, defines early intervention services to include services in the home, in the community, and in other settings for children birth to 3 years old. The plan used to guide the intervention services of a child under the age of 3 years is called the individualized family service plan (IFSP). At age 3, children transition from the IFSP to the individualized education program (IEP). As long as the child remains eligible for special education services, the child will be qualified to have an IEP until he or she graduates from high school.

EI programs and services may occur in a variety of settings, but there is an emphasis on services taking place in the natural environments for the child and their family or caregivers. These EI

programs are proven to be most effective when started as soon as the delay or disability is identified for the child. Services may be preventive in remediating existing developmental problems or preventing their occurrence. These interventions can occur in the home, school, community, or other settings.

Naturalistic Settings and Parent Training

Skill acquisition in naturalistic or inclusive settings and parent training are cited in the literature as the two strongest benefits to providing HBEI services. Moreover, providing HBEI services allows service providers to target skills using routines and materials that are familiar to the child. Additionally, service providers are able to consult with family members to identify common language to use during routines, thereby maintaining continuity between the targeted home visits with the service providers and the everyday follow-up practice with the family.

HBEI services are cited as advantageous in facilitating skill acquisition because they increase (a) parental opportunities to practice targeted skills, (b) the likelihood of skill generalization, and (c) inclusive practices by targeting skills that will facilitate a child’s full participation in family activities. Moreover, service providers can support parents by encouraging practicing of skills that the child is currently acquiring in the child’s natural environment.

During home visits, service providers and family members can review and discuss components that are necessary for the child’s success as indicated on the IFSP. Some examples of the aforementioned components include (a) levels of assistance necessary to use with the child when working on a targeted skill, (b) specific language or phrases to be used with the child in order to elicit a specific desired response, (c) intentional plans to provide multiple opportunities for the child to practice a skill that is still developing within the child’s repertoire, and (d) parent behaviors that are necessary to promote learning.

It is well documented that parents and primary caregivers are the most influential teachers most children will ever encounter. Training families to actively participate in practicing targeted skills in the natural environment can result in positive child outcomes and empowered families. However, while it is critical to provide families with specific targets to work on for the week, it is just as imperative that the service provider not overwhelm the parent with too many “homework” activities.

Working in a Family's Home

The family–service provider relationship is highly unique in that the intervention services are delivered within the comfortable, safe family space. Consequently, the service provider and family must cultivate a relationship with clear roles and responsibilities while maintaining respect, trust, and sensitivity. For example, the home-based interventionist must be prepared to be informed of or witness to highly personal and private family matters (e.g., parental discord). Because of the unique position of working closely with families in the home, service providers are encouraged to become well versed and confident in their profession's code of ethics.

HBEI providers' professional organizations and accrediting bodies appreciate the unique ethical considerations faced by early interventionists when working closely with families. Many of these organizations have created codes of ethics for professional members; however, translating ethical conduct into practice, particularly when the interventionist is working in the home, requires highly self-reflective practices and consistent, respectful collaboration with families.

When working in the home with a family, the early interventionist will witness many common practices within the family that may be attributed to the family's culture or simply the family's unique dynamics. The HBEI provider is encouraged to use her own judgment while observing family practices and reframe her “lens” to maintain a position of respect and sensitivity to the unique dynamic of the family. Moreover, HBEI providers will want to consider what they already know or understand

about families' cultural backgrounds and be prepared to make adjustments to service delivery as necessary. For example, a male service provider would likely want to schedule a teaching session in the home of a Muslim family and some Christian families when an adult male family figure is present in the home during the time of the teaching session.

Another critical ethical consideration for the HBEI provider is the issue of family privacy and confidentiality. As an HBEI provider, one has been invited into the family's home and trusted to participate in a highly sensitive area of their life. Service providers are to behave as utmost professionals and adhere to strict standards of confidentiality. Finally, any professional working with children is obligated to use proper channels to report any suspected abuse or neglect of a child.

HOMELESSNESS

Homelessness is a living condition in which children and youth as individuals lack a fixed, regular, and adequate nighttime residence. The McKinney–Vento Homeless Assistance Act (42 U.S.C. §11434a) identifies homeless children and youth as those who

- share the housing of other persons due to the loss of housing, economic hardship, or a similar reason;
- are living in motels, hotels, trailer parks, or camping grounds due to the lack of alternative adequate accommodations;
- are living in emergency or transitional shelters;
- are abandoned in hospitals;
- are awaiting foster care placement;
- have a primary nighttime residence that is a public or private place not designed for or ordinarily used as a regular sleeping accommodation for human beings;
- are living in cars, parks, public spaces, abandoned buildings, substandard housing, bus or train stations, or similar settings; and
- are migratory children who qualify as homeless because they are living in circumstances described in the previous clauses.

Homelessness has always existed, but children who are without a home have never received adequate attention in early childhood education systems. Researchers estimate that more than 500,000 children between the ages of birth and 5 years in the United States are homeless in the course of a given year. Children who do not have stable living environments experience more health problems, developmental delays, and behavioral problems than children living in low-income families with homes.

According to the U.S. Department of Education, 1.4 million homeless students were enrolled in public schools in the United States during the 2013–2014 school year. Families make up roughly one-third of all people without homes in the United States, and 84% of families experiencing

homelessness are headed by women, according to the National Center on Family Homelessness. Many of these families are headed by single females under 30 years of age who have suffered from physical abuse, mental illness, substance abuse, or social ostracism. When mothers of young children suffer from any one or more of these conditions, nurturing relationships are often adversely affected.

Historical Perspective of Homelessness

During the Great Depression, transient homeless were mainly young men (and a small number of women) who moved from place to place like nomads in search of employment. Many of these individuals left their parents' homes in order to ease economic hardships. They also left because they saw no viable employment options in their hometowns.

When the United States entered World War II, the homeless population was drastically reduced because many young men either were drafted into the Army or were employed in the war-booming industries that built supplies and weapons, causing the homeless population of the 1930s to almost disappear. Although fewer people were homeless during this period, the homeless population was now mostly made up of elderly individuals.

Most homeless people from the 1950s through the 1970s had shelter, though it was inadequate. Few lived out in the open or in public places. Even though the postwar economy continued to expand, homelessness still persisted, especially among older and alcoholic men.

In the 1980s, a new version of homelessness materialized exhibiting very different characteristics. It became more common for those without homes to live in doorways, in cardboard boxes, abandoned cars, in railroad or bus stations, and other public places. These changes in living arrangements were juxtaposed with a changing perspective from law enforcement, and public inebriation, loitering, and vagrancy were common charges against homeless individuals.

However, the major change in homelessness was that increasing numbers of women and young families (with children below age 6) were being

counted among the population. More women applied to public welfare departments for aid and shelter. Diverse ethnic groups make up the majority of homeless families, especially those who are chronically homeless. Ninety percent of women who experienced a period of homelessness within one Philadelphia shelter were African American. Some experts argue that the overrepresentation of African American women among homelessness parallels their overrepresentation living in poverty.

Homelessness Today

With more young families represented in the homeless population at the beginning of the 21st century than single men, the elderly, or individuals with special needs, homelessness has changed substantially. Policies and programs have been put into place for homeless families. For example, the U.S. Department of Health and Human Services and U.S. Interagency Council on Homelessness spearheaded new advocacy efforts with the convening of its series of Homeless Policies Academies between 2001 and 2013. They focused heavily on addressing the needs of homeless children and families through collaborations between federal, state, and local policy makers. Research continues to focus heavily on the characteristics of these families, the barriers that they face, how the social environment affects them, and how to meet their needs.

Early Childhood Education and Homeless Populations

Young children who do not have stable living environments also have multiple other risk factors, such as experience with violence, poor physical health, hunger, nutritional deficiencies, emotional and behavioral difficulties, anxiety, and depression. These factors contribute to delayed development and educational disruption. The McKinney–Vento Homelessness Assistance Act of 2000, which expanded the services provided under the Stewart B. McKinney Homeless Assistance Act of 1987, has increased educational stability for some children.

The National Association for the Education of Homeless Children and Youth states that the most

common age for a person in the United States to stay in a homeless shelter is during infancy. Mothers in shelters are typically young, have very low income, and were not likely to have received adequate prenatal care, leading to a higher risk of premature births. Most children without stable homes do not stay in shelters due to limited availability and strict rules. It is much more likely that families with young children would be staying with others because of lack of a place to go. These situations offer little stability and the family may be moving in with others after a few weeks or months.

Accessing early learning programs for their children is a challenge that many homeless parents are not able to meet. The high rate of mobility, lack of transportation, fear, and shame about their circumstances all contribute to this difficulty. In about half of all states, families with no countable income are still billed for child care copayments. Without access to child care, mothers are often not able to seek employment.

Massachusetts and Oregon have developed unique policies to ensure access to high-quality early care and education programs for children who are experiencing homelessness. The Massachusetts plan involves interagency collaboration, engagement of the private sector, and academic research. Oregon has focused on developing local systems and encouragement of collaboration across various sectors of early childhood education.

Although parents who do not have stable living arrangements may not be able to participate in traditional ways with their children's education, some strategies for teachers that have been successful include setting up a parent lounge for support groups to meet, providing reading materials about child development and lists of local resources for family services, creating a toy lending library, providing clothing/food/first aid materials banks, and assuring confidentiality when helping families to obtain services.

IDENTIFICATION OF SPECIAL NEEDS

Identification of special needs refers to the process of identifying children who have a disability or are at risk for developing a disability that can affect any or all areas of development and learning. Research provides strong evidence that early care and intervention can lessen or eliminate the negative impact of having a disability or being at risk for having one. This is why it is so important to identify all children with special needs as early as possible. This entry provides information about the process and procedures used to identify children with special needs, including those that are mandated by law and considered best practice in the field.

Introduction

The importance of growth and development in the early years is universally accepted. Engaging opportunities to interact with individuals and the environment are critical. The most important intervention for all children is providing high-quality learning environments. However, many children may have internal or external factors that inhibit optimal development or place stress on the developmental process. Children who have delays or a disability or are at risk are at a disadvantage and may need additional appropriate interventions. Longitudinal research provides evidence of

the importance of identifying children with special needs as early as possible. This has resulted in laws to mandate and support the identification of young children with special needs.

Legal Basis

The Education for All Handicapped Children Act (EHA) was passed in 1975 and provided the requirements, funding, and guidelines for the education of students with disabilities. This law mandated six principles for the identification and education of individuals with disabilities:

1. Free appropriate public education
2. Nondiscriminatory evaluation
3. Development of an individualized education program
4. Education provided in the least restrictive environment
5. Implementation of due process procedures
6. Parent participation

This law initially mandated these provisions for children ages 3 to 21. However, when Congress reviewed the impact of the law 10 years later, it became very clear that the preschool age and younger populations were not being served adequately. In 1988, an amendment to EHA enhanced the requirement for states to provide services to

children ages 3 to 5, and provided monetary incentives for the states to provide services to infants and toddlers. The current legislation, the Individuals with Disabilities Education Act, is known as IDEA. The two parts of this legislation that affects early childhood are known as Part B and Part C. Part B provides the guidelines for services for ages 3 to 21, and Part C provides the funding and guidelines for early intervention services for infants and toddlers. The first step in providing appropriate services for young children with special needs is the evaluation process to identify the children that need these interventions.

Identification Process

Screening

The first step in the evaluation process to determine if a child is delayed or has a disability is known as screening. *Screening* is a brief formal or informal assessment to determine if a child should be referred for a comprehensive evaluation in one or more sensory, developmental, or academic areas. In general, screenings are evaluated by a pass/fail system using a predetermined cut-off score or criteria. If a child passes, no further action is required. If a child fails the screening in any or all areas, the child is flagged, and a referral for more comprehensive assessment is initiated. A parent or guardian must give written permission for further evaluation to begin.

Because of the brief nature of screening, errors can occur. A child may “fail” the screening, be referred for further testing for a suspected problem, but after comprehensive testing, is determined to be within normal limits. This is called a *false positive* error. In contrast, there could also be a *false negative* error. This occurs when a child “passes” the screening, but in actuality does have a delay or disability. The child does not receive the comprehensive assessment and thus does not receive the special services he or she may need.

Initial screening will usually begin with vision and hearing. This is important because if a child has a vision or hearing problem, other developmental and academic areas would be affected. For

example, a child may have a hearing impairment due to middle ear infections and be exhibiting a speech problem. If the hearing loss is remedied by placing tubes in the child’s ears, the speech problem may resolve without intervention.

Comprehensive Diagnostic Evaluation

A comprehensive evaluation is initiated in all areas that have been flagged during the screening process. For example, if a preschooler failed the Speech/Language and Motor areas of the screening process then a speech-language pathologist would complete a comprehensive speech and language assessment and a physical therapist would complete a fine and gross motor evaluation. This will entail the use of valid and reliable assessment tools and procedures, and can include both formal and informal assessments.

All assessment data and other relevant information are gathered and shared with the parent and a team of professionals who are working with, or anticipated to work with, the child. This assessment information includes the comprehensive evaluation, a review of records, observations of persons interacting with the child, medical history, and so on. The purpose of this team process is to make informed decisions regarding the child’s development and needs.

Determination of Eligibility for Services

The assessment information is first reviewed to determine if the child meets the criteria for any of the categories identified as a disability in the law. For example, one of the criteria to determine whether a child has an intellectual disability for ages 3 to 21 is an IQ score below 75 or 70 (depending on the state). Each special needs category has specific criteria that must be met in order to designate a child with a specific disability. Criteria may vary from state to state and can mean a change in a child’s eligibility if the child relocates.

If the child does not meet the criteria for a disability category the team will still identify strengths and weaknesses and recommend further monitoring. If the child does meet the criteria as a child

with a disability under the law, then a second review of the assessment information will begin to determine intervention planning.

Intervention Planning

Once a child is diagnosed as having a disability, the law mandates that a written intervention plan be developed. This plan is known as an individualized family service plan (IFSP) for children birth through age 2. If the child is over 3 years of age an individualized education program (IEP) is developed.

Process for Identification of Special Needs Unique to Infants and Toddlers

The federal law mandates that any child, birth through age 2, that is identified with a developmental delay is eligible for early intervention (EI) services. The law also encourages a comprehensive system that monitors children at risk for a developmental delay. Each state must establish the criteria for eligibility. Part C legislation mandates a system to locate children who may be eligible for EI services. This system is known as *Child Find*. Child Find provides developmental information to all families and agencies involved with young children. It also establishes a structure for evaluation beginning with a referral for sensory and developmental screening.

Referral/Screening

Every child born in a U.S. hospital is screened by physicians using the Apgar scoring system. Newborns are rated for appearance (color), heart rate, reflex irritability, activity, muscle tone, and respiratory effort. This score is used to determine if further medical assistance is warranted. If there is reason to believe that continuous monitoring or services are needed, a referral is made to Child Find. Most premature infants and infants with other neonatal risk factors will be referred for further monitoring.

Children with established disabilities such as Down syndrome or cleft palate are easier to locate because of early referrals from medical

professionals and social service agencies. Milder developmental delays may go unnoticed. Child Find utilizes community outreach and education to help find children with milder delays. Brochures and public service announcements are often available in settings and events frequented by families.

Child Find sometimes offers mass screenings in public settings such as community centers or public schools. Screening usually takes 10 to 15 minutes and can be completed by a formal or informal process. At this age, some information will be acquired through direct observation but most will be provided by the parent or caregiver. The Child Find screening process also involves gathering information from the families about their concerns about children's well-being and development. This can be accomplished through questionnaires and interviews. The screening process will determine if the child does not need further assessments, if the child should continue to be monitored, or if the child should receive a more comprehensive diagnostic evaluation.

Comprehensive Diagnostic Evaluation and Assessment

A multidisciplinary evaluation will be conducted for all children who have been indicated by the screening if the parent gives consent for such evaluation. Children who fail the hearing or vision screening are referred for an evaluation by an audiologist or optometrist, respectively. If there are other areas of concern, an evaluation of all developmental areas, including cognitive, communication (speech and language), motor, social-emotional, and adaptive, is completed. The multidisciplinary team may consist of a psychologist, developmental specialist, speech-language pathologist, physical therapist, and occupational therapist. The evaluation should include a variety of assessment tools and procedures including informal parent report. Best practice includes observation in natural environments and play-based assessment, and incorporates the family in the assessment process. Family assessments are also conducted to determine the resources, priorities, and concerns of the family.

Eligibility

States are discouraged from identifying infants and toddlers by a disability category. Children are eligible for services if they have a diagnosed physical disability such as Down syndrome or a developmental delay (DD). Because the definition of DD was left to the states, a child's eligibility for services varies from state to state. Often the criteria for determining eligibility are defined as the number and/or percentage of months of delay. Some states also have eligibility for children at risk of experiencing developmental delays.

Individualized Family Service Plan

When a child is found eligible for EI, then an IFSP is written. A service coordinator is selected to be the contact person for the family to ensure access to and coordination of services. A meeting is scheduled to complete the IFSP and includes the family, the service coordinator, at least one member of the evaluation team, and any other relevant service providers. This team reviews not only the child's strengths and weaknesses but also the family's resources, concerns, and priorities. The goal of this process is to provide families with the information they need to make informed decisions regarding the services they want for their child and themselves. This team identifies expected outcomes, the services needed to achieve these outcomes, and how to determine if the outcome is met. Any direct services to the child will occur in natural environments such as the home. Services may include but are not limited to family training, health services, nutritional assessment, family counseling, physical therapy, speech-language therapy, occupational therapy, transportation, and assistive technology.

Process for Identification of Special Needs Unique to Preschool (Ages 3–5)

Screening/Referral

Similar to EI, the identification of children with special needs begins with a referral to Child Find. Local education agencies (school districts) are

generally responsible for providing Child Find services for ages 3 to 5 prior to entry into kindergarten. Parents, preschool teachers, or pediatricians or other medical personnel are the common referral agents. Screening may occur individually or in small groups in community-based settings.

Screening for this age group includes sensory ability, all developmental domains, and school readiness skills. If any area indicates concern in the screening step, then a referral for more comprehensive assessment is generated. As mentioned earlier, both false positive and false negative errors may occur.

Comprehensive Diagnostic Evaluation

Parents must provide written permission for an assessment to begin. A multidisciplinary assessment team provided by the local education agency (LEA) conducts the diagnostic assessment. Ideally, this would include parent report, formal and informal assessments, and context-based data collection from multiple sources and settings. Once all the assessment processes are complete, a meeting is scheduled with the parents, assessment team, an LEA representative, and other relevant personnel such as potential providers of services to determine eligibility for services.

Eligibility and Program Planning

The first goal of this meeting is to determine if the child is eligible for services as designated by the federal law, IDEA, as a child with a disability. Categorical designations can be given at this age, but DD is still available as an option until ages 6 to 9, depending on the state.

IDEA lists 13 disability categories under which 3- through 21-year-olds may be eligible for services:

- autism
- deaf-blindness
- deafness
- emotional disturbance
- hearing impairment
- intellectual disability
- multiple disabilities

- orthopedic impairment
- other health impairment
- specific learning disability
- speech or language impairment
- traumatic brain injury
- visual impairment (including blindness)

If it is determined that the child is eligible for services under IDEA, then an IEP is written. The IEP includes a summary of the child's strengths and weaknesses and specifies goals, and identifies services to be provided, intensity and duration of services, and personnel responsible for the implementation of the IEP. Parents are an integral part of this process and must give written permission prior to implementing the IEP. However, unlike the IFSP, the IEP focuses primarily on the child's needs (not families' needs).

Process for Identification of Special Needs Unique to School-Age Children

Early childhood is generally defined as birth to age 8 or 9. Therefore, early childhood also includes the early school-age population. Any infant, toddler, or preschooler who is identified as having a disability and who continues to meet eligibility criteria will have an IEP written yearly by the public school system. However, it is not uncommon for some children to first be identified upon their participation in early elementary school.

Screening/Referral

Most school districts screen all children in the early grades for vision and hearing problems. If the child is indicated by the screening as having a vision or hearing concern, a referral is made to an optometrist or audiologist, respectively. Mild disabilities may not be detected prior to school entry. It is usually the regular education teacher that notices difficulties in academic performance or behavior. When the regular education teacher has concerns, most schools provide a team of professionals to review concerns and initiate a prereferral intervention process. The goal of this process is to determine if there are other methods or programs that would better

assist the child's learning and interactions. This is known as response to intervention (RTI). RTI is not mandated by IDEA but is common practice in most states. If the child continues to have difficulties after several different interventions, then a referral for an evaluation is initiated to determine if special education is indicated.

Comprehensive Diagnostic Assessment

Evaluation procedures are implemented by a multidisciplinary team. The tests and procedures will vary depending on the reason for the referral, screening results, and eligibility criteria. However, two areas that are frequently assessed are achievement and intelligence. Obviously, if other areas of concern such as speech and language, social-emotional, or physical development exist, those will also be evaluated.

Eligibility and IEP Program Planning

A multidisciplinary team that includes but is not limited to the LEA representative, a regular education teacher, a special education teacher, parents, and other appropriate personnel such as a physical therapist reviews the assessment results to determine if the child meets the eligibility criteria under IDEA. If the child is determined to be eligible and the parents provide written permission, the team develops an IEP just as was described for preschool-age children.

Conclusion

Although the processes are similar in all age groups as described in the introduction, there are some important differences. The identification process for infants and toddlers focuses more on the family's needs and resources and results in an IFSP. There are also differences in the categories available to determine eligibility. Preschoolers are primarily assessed in developmental areas whereas assessment for school-age children focuses on academic and behavioral areas. Unique to the school-age population is a prereferral intervention phase known as RTI.

Controversies

The processes for the identification of children in need of special education are not without controversy. The use of disability labels and the stigma attached has been debated for years. There is also concern regarding the overrepresentation of minorities in certain disability categories that is central to the debate regarding whether assessment tools and practices are sensitive to young children who are culturally and linguistically diverse. And finally, there is the question regarding what happens to those children with delays or difficulties who do not meet eligibility criteria and, therefore, are not eligible for services through IDEA funding. Most children will continue to be monitored, but states differ in specialized services that are offered.

IDENTIFYING AS AN EARLY CHILDHOOD PROFESSIONAL

This entry examines the definition of a profession as distinct from other occupations and the interdisciplinary environment of early education. It reviews the development of the early childhood profession and historical shifts that affected professional identity and public perception of professional status. The current status of early childhood teachers as professionals, initiatives to raise status, and indicators of the degree to which teachers of children from birth through age 8 identify as members of the early childhood profession are reviewed.

Professions as Distinct From Other Occupations

Sociology offers two approaches to defining a profession. The sociological trait model proposes that if an occupation has specific traits then it is a profession. Examples of those traits include shared core knowledge and skills, accredited training programs affiliated with institutions of higher education, certification based on demonstrated competency, a professional organization, an agreed-upon code of conduct, and an altruistic call to public service. The structural–functional model proposes that if the public has high stakes in the occupation's work and professional skills are based on a shared core body of knowledge, then the occupation has the responsibility to protect the public by organizing a professional association, developing a code of ethical conduct, and developing professional preparation and a certification system.

Applying either of these models indicates that teaching is a profession, although some would argue

that the professional status of teachers is recent and unstable. In early childhood there are additional lingering questions about whether everyone providing care and education to young children from birth through age 8 is a member of the profession, whether some are paraprofessionals rather than full professionals, and whether the profession is defined by the unifying function of care and education for young children or by the different systems that deliver early care and education.

The Interdisciplinary Environment of Early Childhood Education

Multiple professions or disciplines intersect to deliver early childhood services to young children and their families. These include early childhood educators, social workers and home visitors, pediatricians and pediatric nurses, psychologists and mental health professionals, child development researchers, early childhood policy makers, and public administrators. While this rich, interdisciplinary environment nurtures professional collaboration and deepens each profession's understanding of the needs of children and families, it also creates challenges to identification with a distinct profession of early childhood education (ECE).

Development of the Early Childhood Profession

Kindergarten and Nursery School Movements

The first teachers to identify with and build the early childhood profession in the United States were kindergarten and nursery school teachers. The first kindergartens in the United States were established in the second half of the 19th century along with kindergarten teacher training schools.

The nursery school movement followed in the early 1900s. Rather than an identity based on the kindergarten model, this movement identified itself with the broader history of day nurseries serving factory workers and immigrant families, the founding of the U.S. Children's Bureau, child labor laws, and family social services. Patty Smith

Hill convened leaders of this movement to form the National Committee on Nursery Schools in 1926. This committee became the National Association for Nursery Education (NANE) in 1929 and later the National Association for the Education of Young Children (NAEYC) in 1964. NANE members engaged in the expansion of public nursery schools during the Great Depression of the 1930s and the expansion of child care services under the Lanham Act during World War II.

Child Care Expansion, Head Start, and Rapid Growth of the Profession

After World War II, women were encouraged to leave the workforce. Participation in full-day child care dropped, and the majority of teachers who remained in the profession worked in part-day preschools. Growth was slow during the 1950s but revived with the advent of Head Start in 1964 and the expansion of child care services in the 1970s and 1980s, fueled this time by women's return to the workforce, an increase in the number of single-parent families, and welfare reform policies requiring parents to participate in training or jobs in order to receive benefits.

The early childhood profession maintained its roots in child development and the needs of the whole child, rather than in specific early care and education services or models. During this 50-year period of structural change and growth in the field of ECE (1950–2000), an increasingly diverse workforce dispersed across kindergarten, part-day preschool, child care, and Head Start identified with a shared early childhood profession and its professional association. NAEYC membership grew from 1,000 in 1956 to 6,000 in 1966, to 28,000 in 1976, and to 62,000 in 1989, and reached its current peak of 100,000 members in 2000.

Brain Research, School Reform, and the Growth of Prekindergarten

The evolution of the early childhood profession continues today. Studies of early literacy and brain research promoted new government and foundation

investment in accreditation, quality rating and improvement systems (QRISs), and publicly funded prekindergarten. The current focus on the role of high-quality preschool programs in preparing all children for school entry and success has increased public awareness about the continuum of learning that occurs from birth through age 8 and the need for early childhood professional preparation and state licensure policies to bridge this continuum.

Current Status of the Profession

Professional Standards and Accreditation of Preparation Programs

One of NANE's first publications was the 1929 *Minimum Essentials for Nursery School Education*. During the 1980s, NAEYC developed a series of widely adopted guidelines and standards. These included guidelines for professional preparation in associate degree, baccalaureate, and post-baccalaureate programs (1981–1984); a position statement titled *Developmentally Appropriate Practice in Early Childhood Programs Serving Children From Birth Through Age Eight* (1986); and a code of ethical conduct (1989).

NAEYC's standards for professional preparation were adopted by the National Council for Accreditation of Teacher Education (NCATE) in 1983 and are used today as state standards for approving teacher education programs leading to state early childhood teacher licensure. NAEYC established the Commission on Early Childhood Associate Degree Accreditation in 2006, filling a gap in professional accreditation of teacher preparation.

Professional Credentials

Very little professional preparation is required before employment in child care centers and homes. Instead, state child care policy has focused on defining competencies for the early childhood and school-age child care workforce, creating state child care credentials linked to clock hours of training in core competency areas, and building professional development registries. In the P–12

school sector, state policies clearly require professional licensure with at least a bachelor's degree though few states require early childhood specialization in the early grades.

Two national credentials recognize teachers with early childhood specialization at different points in their careers. The Child Development Associate (CDA) credential recognizes individuals who demonstrate entry-level competencies and can be earned while completing high school. The Early Childhood Generalist certificate offered by the National Board for Professional Teaching Standards (NBPTS) recognizes accomplished early childhood teachers who have at least three years of practice as a licensed professional and demonstrate advanced professional knowledge and skills.

Professional Membership Associations

Early childhood professionals join multiple professional associations. The National Association for the Education of Young Children (NAEYC) is the largest, representing all those who work directly with young children from birth through age 8 as well as early childhood teacher educators, program administrators, advocates, researchers, and policy makers.

Other professional associations represent specialized roles within the early childhood profession. The National Association of Early Childhood Teacher Educators (NAECTE) and Associate Degree Early Childhood Teacher Educators (ACCESS) represent teacher educators. The National Association of Early Childhood Specialists in State Departments of Education (NAECS-SDE) represents state education agency staff with responsibility for early education.

A number of related professional associations have early childhood members, interest groups, or divisions. These include the National Association for Family Child Care (NAFCC), the Association for Childhood Education International (ACEI), the Council for Exceptional Children (CEC) and its Division for Early Childhood (DEC), and the American Montessori Society.

Ethnic, Cultural, and Socioeconomic Diversity in the Profession

The profession faces challenges and opportunities related to its national history and the increasing diversity of the U.S. population. All early childhood professionals need to develop the commitment, knowledge, and skills to support the greater cultural, linguistic, and ability diversity present in today's classrooms. There is also a need to attract, welcome, learn with, and learn from a more diverse teaching profession that better reflects the population of children and families served.

Community colleges offer access to higher education and the profession for currently underrepresented groups. Comprehensive scholarship programs such as Teacher Education and Compensation Helps (T.E.A.C.H.) demonstrate that the educational level of the child care workforce can be raised and turnover rates reduced through strategic investments. Raising the educational level of center- and home-based child care teachers benefits the children they serve, increases identification with the profession, sustains a lifelong career, and can increase ethnic, cultural, and socioeconomic diversity in the profession as a whole.

Initiatives to Raise the Profession's Status

Low wages and high turnover are prevalent in the child care sector of the profession and impact program quality. The Worthy Wage Campaign initiated in 1991 advocated for higher compensation for child care staff and continues today as an activity of the American Federation of Teachers. NAEYC and others call for compensation parity across the child care, Head Start, and P-12 sectors of the field.

The expansion of prekindergarten and support for early childhood specialization for early-grade teachers has potential to lift the public status of the profession. Recent New America Education policy briefs by Laura Bornfreund and colleagues recommend a shift away from kindergarten through sixth-grade schools and toward a reorganization of schools, teacher preparation, and teacher certification to bridge the continuum of early childhood education from birth through age 8 or third grade.

Indicators of Identification as an Early Childhood Professional

NAEYC preparation standards identify five key elements of professionalism: (1) identifying and involving oneself with the field; (2) knowing and upholding professional standards and ethical guidelines; (3) engaging in continuous, collaborative learning to improve practice; (4) integrating knowledgeable and reflective perspectives on the field; and (5) engaging in informed advocacy for children and the profession.

Indicators of identification as an early childhood professional include attainment of professional degrees and other credentials, ongoing professional development, engagement in professional associations and peer networks, a commitment to uphold professional standards in everyday practice, long-term commitment to the field, and participation in advocacy activities.

Specialized preparation increases identification with the profession. Current and future teachers of children birth through age 8 who join early childhood professional associations and pursue early childhood degrees and credentials make a powerful statement of identification with the profession.

Conclusion

The early childhood profession has grown from a small group of teachers inspired by the kindergarten movement to a very large profession that must navigate shifts in public funding, regulation, and support. Early childhood teachers, professional associations, and policy advocates will all play a role in defining the early childhood profession during the era of prekindergarten expansion. In the meantime, early childhood teachers across the child care, Head Start, and PreK-3 sectors of the field appear to be identifying with the early childhood profession.

IMAGINATION

Imagination contributes to the development of children in many ways. In fact, there are numerous lifelong benefits to children's early experiences with imagination. The benefits of imagination are cognitive, social, and emotional. Imagination supports children's creativity, for example, as well as their problem-solving skills and their capacity to anticipate what may happen in the future. With its connection to the capacity for creative thinking, imagination is also involved in adaptability and health, and eventually may manifest itself in innovation and even entrepreneurship. During early childhood, imagination allows children to explore by using counter-factual thinking and fantasy. Perhaps most clear is the role of imagination in children's pretending and play. Not surprisingly, then, imagination is directly related to learning and development. Recall here that the benefits are

cognitive, social, and emotional. Children develop social skills and develop emotional maturity, as well as problem-solving skills, when they have adequate time for imaginative play.

Imagination Defined

Imagination is typically defined as the capacity to transcend reality. This implies a connection to creativity, though creativity is more than just imagination. Creativity requires a connection to reality, as well as originality. The transcendence of reality that is provided by imagination can lead directly to originality, but the "standard definition" of creativity holds that all creative things are both original and effective. The transcendence of reality would be very helpful for finding original ideas and options.

Imagination also differs from creativity in that it peaks in early childhood. Certainly, older individuals can use their imagination, but not to the degree that children rely on theirs. The Swiss developmental psychologist Jean Piaget tied imagination to the *preoperational stage of development*. For Piaget, the preoperational stage was second in the progression to maturity. The first stage in his view was sensorimotor; the second, preoperational; the third, concrete operational; and the fourth, formal operational. There are stage theories that propose fifth or sixth stages, but what is most relevant is that imagination is not apparent the first few months of life, when a child relies mostly on reflex and thinking concerns sensation and perception, but then it blossoms.

In fact, Piaget believed that the capacity for imagination probably peaks at around age 4 or 5 years. At that point a child supposedly can be entirely immersed in an imaginative world. The child may not recognize the difference between an imaginary world and reality. Children sometimes believe in their imaginary world and believe that it is reality. The implications of this are quite clear: Children should be allowed to engage in imaginative play, given all of the benefits (e.g., learning and problem solving) but at the same time should be encouraged to recognize the distinction between

what is imaginary and what is reality. Stage theories suggest that children are not capable of making this distinction when they are still in the earliest part of a preoperational stage of development, but they should be given experiences and feedback so that when they are ready to distinguish fantasy from reality, they will have practice and reason to do so.

Imagination and Learning

Most cognitive developmental psychologists, including Piaget, tie the imaginative capacity to learning. Piaget did this by connecting imagination with assimilation. For Piaget, authentic learning is a matter of adaptation. Adaptation in turn involves two subprocesses: assimilation and accommodation. In this view, assimilation occurs when the child experiences new information but does not fully understand it. To understand and adapt, the individual alters the information as it is processed such that it will in fact fit into his or her cognitive system. That allows the child to actually process and think about new information that is not fully understood. The second subprocess, accommodation, occurs when there is understanding and the child changes his or her cognitive system in order to take the new information into account.

In this manner, assimilation and accommodation work together, the end result being adaptation. Adaptation is a form of authentic learning and differs from the more superficial memorization. Memorization can occur when an individual merely records given information but does not fully understand it. For Piaget, this happens quite frequently and is a problem with many educational efforts, because memorization does not indicate that the individual's cognitive system has adapted in a meaningful way. If the individual's cognitive system has in fact adapted, then there is authentic learning, which generalizes and will be retained. Note the implication here for education and all of learning, as well as the connection between assimilation and imagination.

Mature imagination probably works along with other cognitive capacities. In fact, this was the thrust of Lev Vygotsky's theory of development.

Vygotsky described maturity as an increased complementarity of reasoning and logic with the imaginative capacity. For Vygotsky, well-synchronized imagination and reasoning should not be expected until well into adolescence. Vygotsky also felt that social context was quite important for imagination and that the coordination of imagination with reasoning was vital for true creativity.

Imagination in Childhood Setting the Stage for Adulthood

Imagination is often active when a child plays, but it also contributes to pretending and fantasizing, and in what may be its most sophisticated and mature form, in *worldplay*. This is apparent when the child constructs a detailed and elaborate context—an entire imagination world—in which he or she may explore and invent. Worldplay sometimes lasts into adulthood, though this probably depends on the child's worldplay: A child who frequently experiences worldplay is more likely to continue to explore it during adulthood than a child who rarely if ever experiences worldplay. Adult worldplay is also the most common in unambiguously creative adults. They are unambiguously creative in that they do things that are socially recognized as highly original and effective. It is possible that the use of imagination during childhood, including the experience of worldplay, exercises creative talents. For whatever reason, there seem to be lifelong benefits to imagination.

Worldplay is different from other imaginative activities. It involves specific individuals who are usually entirely imaginary and it must persist over time. The world or scenario imagined must be a place that is visited and revisited. Last, and most obviously, worldplay involves a place that is imaginary. It is different from an imaginary friend.

A great deal of research supports the idea that there is a correlation between an adult's capacity to use imagination in an effective way, perhaps for solving problems or as some sort of catharsis, and early opportunities for imagination. These opportunities may allow imaginative play or interacting with an imaginary friend or an imaginary world.

Very likely, children first learn to transcend and transform reality by playing. There are different kinds of play (social, solitary, parallel), but the critical one for imagination is pretend play. In a sense, pretend play is a form of practice. It exercises the imaginative capacities as well as specific skills, which might involve problem-solving or even social situations. Children can explore and even simulate possible experiences in their imaginary play. Longitudinal research by Sandra Russ suggests that play has both cognitive and affective benefits and that these set a foundation for lifelong creative capacities.

Given that imagination represents some transcendence or transformation of reality, an important question involves how imagination can be coordinated with realistic thinking. Clearly, children should not just be imaginative or they would be completely out of touch with reality. At the same time, given all of the benefits of imagination, it is important that they retain the capacity to use their imagination. This would allow some sort of balance of imagination and practicality, which would be an ideal for the mature individual. It might be a kind of coordination where imagination is used but practical and realistic thinking then occurs in some sort of recursive cycle.

Not surprisingly, some of the most recent work on imagination suggests that what is very important is to exercise *discretion*. Discretion is defined as a kind of mindful decision making, and in this view, children retain the capacity to use their imagination, but at the same time are able to exercise discretion. It is mindful, discretionary imagination. These children know when to be creative and pretend and also when to be practical and realistic.

Measurement of Imagination

There are various measures available for research or developmental assessments. Sandra Russ's play scale is very reliable and has demonstrated to offer good predictions, and Thomas Ward, Merrill Patterson, and Cynthia Sifonis have a task called the *alien test* where individuals can be asked to imagine how an extra-terrestrial being would look and how it would survive on Earth. They are able

to draw and describe these aliens. María José Pérez-Fabello and Alfredo Campos also describe a creative imagination scale that has demonstrated good reliability. Research by Mark A. Runco employs several different tasks, adapted from the creativity research such that they target transformational capacity. A "visual" test, for example, presents a figure to the child and asks him or her to name all of the things it could be. The figure is abstract—just a simple line drawing—so all kinds of different ideas can be generated. Transformation is assessed when the child finishes listing ideas but is then asked to imagine the same figure upside down, or turned to the side. The child is also told to "imagine you are above it, looking down," or what would you see if it was huge? Or very small?"

These measures of imagination are being refined in current research. No doubt our understanding of children's imagination, its developmental trajectory, and functions will continue to be explored. The benefits of this line of research are numerous and profound.

IMMIGRANT CHILDREN

An immigrant is someone who leaves one country to live in another on a permanent basis. First-generation immigrants are those who were born outside the United States, and second-generation immigrants are those who were born in the United States or its territories. This entry discusses the demographic characteristics of immigrant children and ways to support them.

The U.S. Census Bureau divides children into two groups by nativity: children born to native parents and those with at least one foreign-born parent. In this categorization, immigrant children include both foreign-born children with foreign-born parents and native children with at least one foreign-born parent. In government and scholarly reports, the term *immigrant children* refers to those who have at least one foreign-born parent, even though most of them are U.S. citizens.

Immigrant children are the fastest-growing group of children in the United States. This changing demographic reality presents both challenges and opportunities. Education, as social commentators, historians, and the courts have noted, plays a

pivotal role in developing and maintaining the fabric of American society. For example, the U.S. Supreme Court in *Plyler v. Doe* (1982) reviewed a Texas statute that denied children whose parents came to the country illegally the right to an education. The Court asserted that an education, the most vital civic institution for preserving our democracy, “provides the basic tools by which individuals might lead economically productive lives to the benefit of us all” (*Plyler v. Doe*, p. 221). The rise in the number of immigrant children in communities and schools in the United States provides both challenges and opportunities in terms of how to effectively educate them.

Demographic Characteristics of Immigrant Children

According to the U.S. Census Bureau, about one in four children under the age of 18 in the United States lived with at least one foreign-born parent in 2014. The vast majority of these young children in immigrant families are U.S. citizens and only about 3% to 5% of them are foreign born or first-generation immigrants, according to the Census Bureau. According to Child Trend Data Bank, the majority of immigrant children, as of 2014, are of Hispanic origin (55%), while a growing number are Asian (16.9%). Most of the remaining immigrant children are classified as non-Hispanic White (16.1%) or non-Hispanic Black (8.5%). Divided by generations, first-generation immigrant children were more likely to be Asian, non-Hispanic White, or Black than second-generation immigrant children, and the second-generation immigrant children are more likely to be Hispanic than first-generation immigrant children (55% and 40%, respectively).

This young population of immigrant children is most likely to have parents who are American citizens, to have Hispanic origins, to live in poverty without health insurance, and to have had less access to preschool. The factors of poverty, lack of preschool education, and potential poor health from not receiving ongoing health care from prenatal care to age 8 create challenges for immigrant children's success in existing educational systems.

Immigrant Children as English Language Learners

Many children in immigrant families use a language other than English at home. A significant portion of immigrant children are English language learners (ELLs) or dual language learners (DLLs: those who are learning English as they learn their home language) and the matter of English language learning poses a challenge to many of them. The extent of this challenge is seen in the numbers of students who are categorized as ELL for instructional purposes. According to the National Center for Education Statistics, in 2011–2012, about one in 10 (9.1%, 4.472 million) students in U.S. public PreK–12 schools were classified as ELL. The top five languages spoken by students learning English are Spanish, Chinese, Vietnamese, Arabic, and Hmong. Three-quarters of ELL students speak Spanish. According to Dale Russakoff (2011), a majority of ELL students are in the elementary grades and 40% of them are 3- to 8-year-olds.

According to Katrina Fortuny, Donald Hernandez, and Ajay Chaudry (2010), among children under age 8, the share of immigrant children was higher among younger children than older children, 60% of young children in immigrant families have at least one ELL parent, and 34% live in linguistically isolated households, in which all adults speak a language other than English. In addition, according to Fortuny, Hernandez, and Chaudry, 27% of young children ages 5 to 8 in immigrant families were DLLs in 2007–2008; among 5-year-olds, 37% were DLLs.

Supporting Immigrant Children

Family involvement is a critical component in immigrant children's success in school and society. Teachers are optimally positioned to act as mediators among the children, families, and school systems. There is a growing need for preparing teachers to develop necessary knowledge, skills, and dispositions to positively and meaningfully interact with immigrant children and their families. Despite ongoing efforts to prepare educators to be culturally competent professionals, practitioners

have identified a need for professional development in how to support immigrant children and their families. According to the National Center for Family and Community Connections with Schools, educators need to respect the cultural values of families, create warm environments, promote positive interactions and ongoing communication, and facilitate accommodations for family involvement such as transportation, translators, and translated documents. Understanding immigrant children's sociocultural and linguistic experiences and their challenges, valuing their home language and culture as assets, and sustaining strong home–school–community partnerships are essential components of supporting immigrant children.

IMMIGRANT FAMILIES AND EARLY CHILDHOOD EDUCATION

According to the U.S. Census Bureau's 2013 American Community Survey, 25% of children under age 6—a total of nearly 5.8 million children—either were immigrants themselves (5%) or were

native born but had at least one parent who was an immigrant (95%). In some states, such as California, these first- or second-generation immigrant children comprise closer to half of all children under age 6. Given the robust evidence that high-quality early childhood education (ECE) programs can boost children's school readiness, there is growing attention paid to the opportunities for accessing such programs on the part of immigrant children and their families. This entry briefly describes the patterns of ECE use and quality for immigrant children, summarizes the evidence of ECE effectiveness for immigrant children, and addresses barriers to ECE access and care quality.

Patterns of Care Use and Quality

As a group, immigrant children are more likely than their native-born counterparts with native-born parents to be living in poverty, with parents who have low levels of education, and to be in a linguistically isolated household where no one over age 14 speaks English "very well" or "well." Such circumstances, as well as other stressors, place many children in immigrant families at risk of not being ready for school when they enter kindergarten, with consequences for their success in the elementary grades and beyond.

While there is great potential for high-quality ECE programs to address school readiness gaps, research using a variety of U.S. data sources consistently demonstrates that immigrant children under age 6 are less likely to participate in formal center-based ECE programs prior to kindergarten entry compared with non-immigrant children. Empirical studies indicate that there is variation across immigrant subgroups defined by country of origin in the patterns of ECE participation. However, much of the gap between immigrant and native children in care use can be explained by a few factors including poverty status, parental education, number of parents, and Hispanic ethnicity.

In terms of the nature of the care and early learning settings, there is evidence that those immigrant children who do participate in formal early learning programs often do not experience the

high-quality environments that support healthy cognitive, social, emotional, and physical development. Programs also may not be equipped to provide care and learning supports that are culturally and linguistically appropriate for the needs of immigrant children.

Evidence of Preschool Impacts for Immigrant Children and Families

An extensive literature documents the short- and long-term benefits from participation in high-quality early learning programs from birth to kindergarten entry, especially for children at risk of starting out in school behind and staying behind. For this reason, we might expect that the same would hold for at-risk immigrant children as well. Increasingly, there is evidence of the benefits from ECE participation specifically for immigrant children. For example, a quasi-experimental evaluation of Oklahoma's universal preschool program demonstrated favorable effects on school readiness for Latino children and for children whose parents spoke Spanish at home. Observational studies based on the Early Childhood Longitudinal Study-Kindergarten Cohort offer further suggestive evidence that high-quality early learning experiences can boost school readiness for immigrant children.

There is less evidence, to date, of the potential longer-term impacts of ECE programs specifically for immigrant children and of the importance of program quality—especially instructional supports for English language learners (ELLs)—in maximizing developmental gains. Rigorous evaluations point to the effectiveness of alternative approaches to language instruction, such as two-way bilingual immersion—in which students learn in both English and another language—compared to monolingual English immersion—in which instruction is solely in English. Another gap in our knowledge is the benefits for immigrant parents of ECE participation. Early care and learning programs offer opportunities to build community and to encourage and model parent engagement that can carry over to the K–12 grades, to provide connections to other community-based resources, and to support parental employment.

Identifying Barriers to Access and Use

Qualitative and quantitative research on ECE use on the part of immigrant families with young children points to a number of potential barriers—structural, informational, bureaucratic, and cultural—to more widespread participation in high-quality ECE programs. The relative importance of different factors may vary across different immigrant subgroups and may change over time as children age. Structural barriers include affordability, availability, and access to care—factors that affect disadvantaged families more generally. Circumstances unique to immigrant families include the fact that many parents of immigrant children are not authorized to be in the country even though their children are U.S. citizens. Employment outside the formal labor market further limits use of child care subsidies or other programs that require employer verification. Limited care options in neighborhoods where immigrant children and their families reside, transportation gaps, as well as the need for care during nonstandard hours (e.g., nights and weekends), may further constrain the care choices immigrant parents make.

Informational and bureaucratic barriers include the multiplicity of programs available to subsidize ECE for low-income children (e.g., Early Head Start, Head Start, state preschool programs, child care subsidies), the complex enrollment processes that accompany the various programs, and the need to certify vaccinations are up to date. Unique cultural factors also likely play a role in ECE choice. Within the Latino community, as well as others, research shows a preference for parental care or care in a home setting by other family members, although such preferences appear to be outweighed by the structural issues described earlier. Preferences for same-language care among some immigrant groups may necessitate family, friend, and neighbor care over formal, center-based programs.

INCARCERATED PARENTS, CHILDREN OF

The number of children with incarcerated parents has skyrocketed in the past few decades, largely as a result of drug arrests and states' "three strikes" laws that require long-term prison sentences for a third offense. The number of women in prison went up by 587% between 1980 and 2011, rising from 15,118 to 111,387, according to the Sentencing Project. Including women in local jails, more than 200,000 women were incarcerated as of 2012. Those working with young children are likely to meet children of incarcerated parents, and can work both in the public sphere and in personal relationships to help them through their very impacted lives.

After a mother's arrest children are typically sent to live with relatives, usually their grandmother, or they go into foster care. If the father is arrested, children usually stay with their mother. If the child has to leave his or her home, the child

knows “this isn’t *my home* and it’s not my family” so he or she is likely to feel out of place and abandoned. It can help a child to visit his or her parent regularly in jail or prison, but it is rare that children of incarcerated parents visit regularly; the trip can be costly, and there may be no one who wants to take the child to visit, or the person the child is living with is too angry at the prisoner to consider helping make visits possible.

Children in families affected by imprisonment often suffer emotional stress, social isolation, difficulties in school, mood changes, regression, and health problems (notably asthma). Engagement in the arts and music can help them express their anxieties and anger, and sports can also lighten the load.

The psychological needs of these children are regularly ignored in institutions, including schools and child care centers. Often teachers and child care center staff don’t get this information while first meeting the child, and sometimes they never know. It is likely that they will be working with a child of an incarcerated parent, however. According to the Pew Charitable Trusts, 2.7 million children under 18 had a parent in jail or prison as of 2010. This represents 1 in every 28 children in the United States. For Black children, the likelihood of having a parent in prison or jail is even higher—1 in 9 Black children had a parent in prison or jail.

The San Francisco Children of Incarcerated Parents Partnership (SFCIPP), a coalition of social service providers, representatives of government bodies, advocates, and others who work with or are concerned about children of incarcerated parents and their families, developed what it called the Bill of Rights for Children of Incarcerated Parents. The bill reads as follows (SFCIPP, n.d.):

1. I have the right to be kept safe and informed at the time of my parent’s arrest.
2. I have the right to be heard when decisions are made about me.
3. I have the right to be considered when decisions are made about my parent.
4. I have the right to be well cared for in my parent’s absence.
5. I have the right to speak with, see and touch my parent.
6. I have the right to support as I face my parent’s incarceration.
7. I have the right not to be judged, blamed or labeled because my parent is incarcerated.
8. I have the right to a lifelong relationship with my parent.

There is no state in the United States where these simple, fair rights are honored in law or in everyday practice. Severe as the conditions are for a sizable portion of U.S. children, there is no public outcry on their behalf.

One policy change that could help children of incarcerated parents would be permitting parents who are no danger to their children to serve time at home, where they can continue to care for their children. Another is making sure children can see their parents regularly by supplying buses with counselors to take children to and from jail and prison visits, or pairing community volunteers to drive a child to the prison, see them through the visit, and safely return them home. These visits can often be very upsetting, but also necessary to parent–child relationships.

Early childhood educators can indirectly support children of incarcerated parents by finding ways to provide art, music, and sports experiences. Young children of prisoners often fear disclosing their story to others, experiencing shame and distrust. They may try to give the impression that they need no help from anyone. Tone matters in talking with children in pain, so speaking to the child sympathetically may make him or her more willing to talk. It is also important to know what the parent or guardian caring for the child has told the child about the parent’s incarceration.

The child with an incarcerated parent needs to know that having a parent in prison isn’t what defines him or her. If the child knows that an educator cares, is interested in his or her welfare, and will listen to what needs to be said, that will help.

Teachers can lead a discussion about missing people. The child with a parent in prison isn’t the only child who longs for someone absent—people

die, they move away, they divorce. It matters to the child of a prisoner that there are other people who miss people. He or she is not alone. Teachers can invite children to draw or paint people they miss and display this work in the classroom. Thinking with love about the people who are missed is an activity that can benefit all the children, and include them in the human story.

Inclusion

See Early Childhood Inclusion

INDIVIDUALIZED FAMILY SERVICE PLAN AND INDIVIDUALIZED EDUCATION PROGRAM

Individualized family service plans (IFSPs) and individualized education programs (IEPs) are both processes and documents that reflect the American belief that young children with disabilities or developmental delays and their families can benefit from early intervention programs. These processes ensure that children and families have a right to appropriate, integrated, and even free supports in their community, regardless of the challenges experienced early in a child's life and a family's socioeconomic status.

The IFSP is associated generally with children under age 3 and their families, although states can choose to extend its use to older children. The IEP is associated with children 3 to 21 years, who are eligible for public school special education services. This entry focuses on the IFSP for infants and toddlers and the IEP for preschool populations 3 to 5 years of age. It provides an overview of the rationale for these individualized plans and information about their key components, as well as detailing the similarities and differences in the IFSP and IEP.

The Individuals with Disabilities Education Improvement Act (IDEA) was passed into law as Pub. L. 108-446 in 2004. This statute was a reauthorization of earlier versions of the IDEA. The law was originally enacted in 1975 as Pub. L. 94-142 or the Education for all Handicapped Children Act (EHA) as a federal response to Section 504 of the Rehabilitation Act in 1973, and called for free appropriate education for all children with disabilities ages 5 to 21 years. The EHA mandated public schools across the country to offer special education supports in the least restrictive environments for learning to children with any type or severity of disability. Individual states responded in subsequent years with state laws to reflect the federal requirements that included the use of an IEP.

Multiple reauthorizations of IDEA have occurred since 1975, with Pub. L. 99-457 in 1986 being the most significant for children under the

Table 1 Comparison of IFSP and IEP Components

	<i>IFSP</i> (Birth to Age 3 Years)	<i>IEP</i> (Ages 3 to 5 Years)
Eligibility	Multidisciplinary assessment, with parent consent, confirms child's developmental progress/delays, and/or a review of medical records confirms diagnoses and/or conditions highly associated with delays and disabilities. Assessments may be from one or multiple agencies but results must reflect state criteria for eligibility. At states' discretion, infants/toddlers at risk for delays due to environmental factors may be eligible.	Assessment, with parent consent, of <i>child's educationally relevant developmental skills for school and social success</i> . Team assessments and document reviews are completed by <i>public school professionals</i> who consider state eligibility criteria for students with disabilities.
Present Abilities	IFSP statement of child's abilities across developmental domains of cognition, communication, social-emotional, adaptive, and physical development including vision, hearing, and health. Information based on objective data from interview, observation, or direct testing and clinical opinion.	IEP statement of child's present levels of pre-academic achievement and functional performance and how disability influences participation in preschool-relevant activities. Information based on observation, interview, and/or direct testing of child's abilities.
Strengths, Concerns, and Needs	IFSP statement of family's and child's strengths and needs based on child assessments <i>and family-directed assessment of family routines, resources</i> , priorities, and concerns in meeting child's developmental needs.	IEP statement of child's developmental and pre-academic strengths and needs, and parental concerns and priorities for their child's education.
Desired Outcomes/Goals	IFSP listing of measureable desired outcomes expected <i>for the child and the family</i> . Functional outcomes <i>should reflect family concerns</i> and not a child's failed test items.	IEP listing of measureable annual goals, and possibly short-term objectives, for academic and functional needs that <i>target student's access to and progress in the curriculum for all children</i> . Goals should <i>reflect functional challenges associated with disability and educational success</i> and not simply child's failed pre-academic test items.
Progress Monitoring	IFSP-documented criteria for determining outcome achievement, and the timeline and measure for checking progress.	IEP-documented criteria for determining goal achievement and the timeline and measure for checking and reporting progress to parents.
Supports and Services	IFSP listing of <i>supports and services, available at no cost to family or on a schedule of sliding fees, to meet the needs of child and family</i> . Can include services from education, health, and social service agencies as well as informal networks and resources.	IEP listing of <i>free public school special education and related services</i> (necessary program modifications, material adaptations, and/or special instruction or supports), provided to/for the child, by classroom or consulting teachers and specialists.

Note: Italicized words highlight key differences.

(Continued)

Table I (Continued)

	<i>IFSP (Birth to Age 3 Years)</i>	<i>IEP (Ages 3 to 5 Years)</i>
Duration/ Intensity/ Frequency	IFSP-documented dates for the beginning and duration of each professional service; includes how often, how much.	IEP-documented dates for the beginning and duration of each school service/support; includes how often, how much.
Learning Environment	<i>Natural environments</i> should be used for advancing children's development. This would be home and community settings typical of same-age peers who have no disability. IFSP must include justification when supports cannot be provided in natural learning environments.	The <i>least restrictive environment (LRE)</i> should be used to support child's participation and learning in an education curriculum with his or her peers to the maximum extent possible for satisfactory learning. This may require settings with variable ratios of disabled to nondisabled children. IEP must include justification when child will not participate in fully inclusive early childhood programs and activities.
Providers	IFSP listing of <i>persons</i> responsible for individual supports, as well as persons or agencies responsible for payment of professional IFSP services.	IEP listing of <i>public school teachers, specialists, and persons</i> responsible for implementing IEP services.
Coordinator	Families are entitled to a <i>services coordinator</i> whose responsibilities include documenting meeting discussions into an IFSP and ensuring family access to IFSP-specified supports/ services. This person <i>may have a dedicated role as coordinator</i> or a blended role on the IFSP team as both a provider of services and services coordination.	A <i>case manager</i> is designated from among those providers listed on the IEP for delivery of special education or related services. The case manager acts as the family's primary contact and ensures parents receive progress reports and meeting notices, and their concerns are addressed in IEP discussions and documents.
Consent	Parents must give consent for IFSP services to be implemented. Parents are under no obligation to agree to recommended services nor continue services outlined in the IFSP. Written request to discontinue services does not preclude later reevaluation and development of a new IFSP.	Parental consent is necessary for implementation of any IEP services. Parent is not obligated to agree to recommended special education and related services nor continue such supports once initiated. A parent's written request for discontinuation does not prevent later request for reevaluation and IEP development.
Transitions	Families can expect a supported transition of relevant services <i>from IFSP community agencies to public school IEP services</i> if the child continues to need them at age 3 years. Steps in transition process should be <i>outlined in IFSP at least 6 months in advance</i> . At parent request, service coordinator can ensure <i>IFSP representation at initial IEP meeting</i> .	IEP case manager can assist parent and receiving teachers in planning <i>transition to kindergarten</i> , should the child continue to need special education.

	<i>IFSP (Birth to Age 3 Years)</i>	<i>IEP (Ages 3 to 5 Years)</i>
Regular Reviews	The IFSP progress must be <i>reviewed every 6 months</i> , or more often if situations warrant or family requests it. In addition, a meeting must be held <i>at least annually to evaluate the need for continued or revised IFSP</i> for child and family.	The IEP must be <i>reviewed at least annually</i> to determine if goals are being met, or more often if the situation warrants or parent requests it. <i>Every 3 years a full review, including reevaluation</i> of special education eligibility, is required, <i>unless</i> parents and IEP team agree reevaluation is unnecessary. Reevaluation for kindergarten supports is not necessary in all cases.
Meetings	IFSP meetings are to be held in places and at times convenient for the family. <i>The IFSP meeting may not be held without the family.</i>	Steps must be taken to ensure one or both parents are present at IEP meetings. Meetings are scheduled at mutually agreed-upon times and places or use conference telephone calls or webcasts to engage parents. <i>If neither parent can attend, the district can proceed without them</i> but must document all efforts to include the parents.
Meeting Participants	IFSP meetings must include at least: Child's parent(s) Family members at parent request Family/child advocate at parent request Services coordinator Persons involved in conducting evaluations Persons involved in providing services	IEP meetings must include at least: Child's parent(s) Others at invitation of parent or district Family/child advocate at parent request Child's primary teacher, be it public school preschool, Head Start, day care, etc. Case manager Persons involved in conducting evaluation Special education teacher or related school provider <i>Representative of school district</i> who can commit district funds for special education and related services
Calendar of Services	IFSP services are <i>to be provided year-round without interruption</i> in intensity or qualified providers and not modified for any reason unrelated to the child's needs (e.g., service provider availability or scheduling).	IEP services are provided only during a school-year calendar. Extended school-year services (breaks, summers, or extended day) must be justified by the IEP team as necessary to prevent loss of critical skills and sustain child's educational progress.

age of 5 years. The 1986 IDEA Amendments established section 619 to Part B of the law, lowering eligibility for free and appropriate education to children 3 years of age. These amendments also

added a section (now Part C) dedicated to requirements for states that chose to coordinate services for children birth to age 3 with disabilities or developmental delays and their families. This part

of the law viewed the IEP as inappropriate for this age group, since the concerns and needs for this very young population focused on the children's development and the families' abilities to meet their children's developmental needs, and successfully access and integrate community resources from agencies and providers independent of or in partnership with public schools. An IFSP was deemed a more appropriate process and document since it highlighted the partnership roles families would play with professionals to address family-identified needs for the *family* in order to influence children's developmental trajectories and eventual school readiness and social competence.

Desired Child Outcomes of IFSPs and IEPs

The U.S. Department of Education requires annual reports of accountability describing outcomes of early intervention programs for children with disabilities. Annually, states must report the percentage of children exiting Part C IFSP and Part B-619 IEP programs who demonstrate gains as a result of their enrollment in these services. The intent of IDEA is to have IFSPs and IEPs guide service providers and families toward desired outcomes while simultaneously addressing individual concerns and needs. Specifically, the reports must address the following child and family outcomes.

Child Outcomes

- Positive social-emotional skills and relationships
- Acquisition/use of early cognitive and communication knowledge and skills (and early literacy for preschoolers)
- Use of appropriate behavior and skill to meet own needs

Family Outcomes

- Know their rights
- Effectively communicate their children's needs
- Help their children develop and learn

IFSP and IEP Components

The IFSP and the IEP processes begin with assessment of a child's eligibility for services and then proceeds, if the parent is interested, to development of a document summarizing family and provider discussions and decisions on how to address agreed-upon desired outcomes and goals. The IFSP and IEP have some similarities but also some important differences. Table 1 outlines key components of each; italicized words highlight key differences.

INEQUALITY FROM BIRTH

Inequality in infant health in the United States is much higher than in similarly wealthy countries. There are large disparities in infant health by race and socioeconomic status. For example, relative to non-Hispanic White mothers, African American mothers are 90% more likely to have a low birth weight birth (defined as less than 2,500 grams) and 70% more likely to have a preterm birth (defined as less than 37 weeks gestation). Unmarried mothers and those with low education levels have higher rates of adverse birth outcomes relative to their married and more educated counterparts.

Disadvantage in early-life health often translates into poor adult outcomes. Therefore, policies that target early-life conditions, especially among vulnerable populations, may ameliorate intergenerational persistence of economic disadvantage and reduce inequality.

Lasting Impacts of Early-Life Health

The link between early-life health and adult well-being was first formalized by David J. Barker, a British physician and epidemiologist, who coined the phrase “the fetal origins hypothesis.” Barker argued that adverse *in utero* conditions can “program” a fetus to have metabolic characteristics that are associated with future disease. Economist James Heckman has further argued that there are important dynamic complementarities between investments in children at different stages of development. This means that initial health endowments raise the productivity of investments at later ages, making it increasingly difficult to overcome initial differences in health.

A large body of research shows that *in utero* and early-life health affects individuals’ life cycle outcomes. For example, several epidemiological studies have compared cohorts who were *in utero* during the 1944 Dutch famine to cohorts who were born just before or after. These studies show that those exposed to the famine *in utero* had higher rates of obesity, cardiovascular disease, and mental illness at age 70.

Economists have looked at the effects of *in utero* exposure to other types of events. For example, one study showed that cohorts exposed to the 1918 U.S. influenza epidemic *in utero* had lower educational attainment, adult earnings, and were more likely to receive disability and welfare benefits relative to cohorts born in surrounding years. Other studies have demonstrated that increased exposure to air pollution in early life reduces high school test scores and earnings at age 30. Exposure to lead and radiation in early childhood similarly negatively impacts adult socioeconomic status. Finally, income in early life matters as well. One study shows that having access to the food stamps

program at birth improves health and measures of economic self-sufficiency in adulthood.

Other research has shown that differences in early-life health measures translate into differences in adult outcomes. Birth weight is seen as a summary measure of health at birth, and one study comparing birth weight differences between twins showed that a 10% increase in birth weight increases adult full-time earnings by 1%.

Interventions

The United States has a number of policies that affect early-life health. The Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) serves low-income pregnant women and children through age 5, and provides benefits that can be used to buy nutritious food. Recent research shows that access to WIC during pregnancy decreases the probability of a low birth weight birth by 8% to 14%.

Family leave policies provide time off from work so that new mothers can prepare for childbirth and stay home to care for their newborns. These policies are important because most low-wage women do not have access to any employer-provided paid time off from work. Although the United States does not have a national paid family leave policy, the 1993 Family and Medical Leave Act (FMLA) grants 12 weeks of unpaid job-protected leave to eligible workers. Research shows that the introduction of FMLA led to improvements in infant health among children of highly educated and married women, who could afford to take unpaid time off work. Paid family leave, however, can improve early-life health among disadvantaged populations. One study shows that paid maternity leave benefits offered through the Temporary Disability Insurance (TDI) system in five states since 1978 reduced the incidence of low birth weight and preterm births among minority and unmarried mothers. California’s 2004 paid family leave program has been shown to increase breastfeeding rates among unmarried and minority mothers with low education levels.

Finally, home visitation programs are designed to provide low-income parents with education about parenting, health, and resource availability through regular home visits by trained staff early in the child's life. One particularly successful program is the Nurse Home Visiting Partnership (NHVP), which targets at-risk mothers and focuses on teaching them how to assess infant health and create safe households. Randomized evaluations of the NHVP indicate that participating mothers are 63% more likely to breastfeed, and their young children experience fewer health problems. The program also has lasting effects on later cognitive ability: Children exposed to NHVP in infancy score 26% higher on achievement tests at age 9 than unexposed children. The success of NHVP is attributed to its highly trained staff and its targeted design; larger-scale interventions with less skilled home visitors have been shown to be less effective.

In sum, mounting evidence points to the lasting consequences of early-life health on adult well-being. Reducing inequalities in infant health may therefore be an important avenue for addressing broader economic inequality. Policies that have been shown to improve early-life health among disadvantaged children include WIC, paid family leave, and nurse home visiting programs.

INFANT AND TODDLER PROGRAMMING

The term *infant and toddler programming* refers to approaches to care and education for infants and toddlers, typically within center-based child care programs. It has gained increasing interest over the last 30 years in the field of early childhood education as the use of child care for infants and toddlers has increased significantly, targeted programs such as Early Head Start and Educare have been created and implemented, and brain and developmental research highlighting the importance of experiences and relationships in the first 3 years of life has been disseminated.

Determining the best way to design child care programs for infants and toddlers requires taking into account the unique developmental aspects and needs of this age group. These needs include developing a secure attachment to a primary caregiver, ability to assert autonomy while maintaining connectedness to a caregiver, exploration of the environment, and family involvement and partnership with care providers. It is through relationships with trusted caregivers that infants learn and grow. Thus, a key component in developing programming for infants and toddlers is defining the ways that relationships and interactions between caregivers and children will be facilitated and sustained. This entry examines a few current models of infant and toddler programs, and presents and discusses current issues in this field.

Approaches to Infant and Toddler Programming

Developmentally Appropriate Practice (DAP)

DAP was designed by the National Association for the Education of Young Children (NAEYC) as a set of principles and guidelines to inform practice in early childhood education instead of a specific approach to programming. However, its principles are pervasive in the field. DAP suggests that decisions about programming for any age group, including infants and toddlers, should be informed by three things: (1) knowledge of child development

generally and across domains for infants and toddlers; (2) knowledge of each child as an individual, his or her unique characteristics; and (3) knowledge of the sociocultural contexts that children grow up in, their families, values, cultural expectations, the understanding that a child is embedded in a sociocultural context even within the classroom walls. In addition, DAP emphasizes the importance of the relationship between the caregiver and child, the set-up of the environment as an important tool for learning, the opportunity for exploration and play, the importance of establishing and maintaining routines, the need for a reciprocal relationship with families, and the ways in which early care and education policies can help or hinder these programmatic needs.

Program for Infant/Toddler Care (PITC)

The PITC was created in the 1980s by J. Ronald Lally, an expert in early childhood education, and today is housed within the WestEd organization, a multifaceted agency aimed at improving education. Lally and colleagues developed the PITC in response to the increased use of center-based child care for infants and toddlers during that time in combination with the recognition that there was a marked lack in guidance for early care and education teachers on how to approach programming for infants and toddlers in child care. Lally and colleagues based the recommendations within PITC on evidence from current brain research that demonstrated the importance of early relationship quality for optimal development as well as on attachment-based theoretical perspectives.

The PITC program has been adapted and enriched by other early childhood experts since it began 30 years ago and continues to be a popular and well-respected framework for infant and toddler programming. It is widely used in Early Head Start programs in the United States and private early care and education programs. The PITC is a relationship-based approach. Its primary focus is on child care policies that facilitate relationships between teachers and children and with families rather than on curriculum, content, materials, or

traditional lesson planning. It focuses on six program policies that are essential to providing quality infant and toddler programming: (1) the assignment of each child to a primary care teacher who is responsible for attending to that child's needs, (2) small group sizes and small teacher-child ratios, (3) continuity of care that arranges for each child to have the same primary care teacher over the multiyear infant and toddler period, (4) individualized care that responds to each child's individual needs rather than attempting to fit the child into a preset schedule for daily routines, (5) cultural continuity that includes a dialogue with families to create continuity between the home and child care setting, and (6) inclusion of children with special needs in the child care setting through providing appropriate accommodations.

Creative Curriculum

The Creative Curriculum was first developed as a preschool curriculum in 1978 by Teaching Strategies, a company that offers early childhood products. The original author was Diane Trister Dodge, founder of Teaching Strategies. In 1997, a version of the Creative Curriculum for use in infant and toddler classrooms was first released.

The infant-toddler version of the Creative Curriculum is used widely in Early Head Start and private child care programs. It is a comprehensive curriculum that provides lesson plans and materials for activities suggested. It focuses on daily care routines, the importance of developing teacher-child relationships, individualization of activities, and has an assessment component that provides a framework for teachers to assess children on a variety of objectives across multiple developmental domains. Additionally, the authors of the Creative Curriculum provide customers with specific alignment documents demonstrating the way in which the curriculum aligns with state early learning guidelines (these guidelines are discussed later in this entry).

Resources for Infant Educators (RIE)

RIE is an organization founded in 1978 by Magda Gerber that advocates for infant and

toddler programming based in the philosophy of care created by Emmi Pikler (the Pikler approach) and her apprentice, Gerber. This philosophy emphasizes a foundational respect for infants as competent and motivated to learn and suggests that adults should not interfere with the process of self-propelled development in infants and toddlers. Essentially, it emphasizes that the way that adults interact with infants and toddlers can encourage their self-motivated drive to learn and develop or hinder this process.

Pikler was a pediatrician during World War II and after its conclusion developed a nursery for traumatized war orphans in Budapest, Hungary. Gerber brought the Pikler approach with her to the United States when she relocated from Hungary. The approach has since evolved into what is known as RIE. The development of RIE was based more on the professional practical experiences of its creators than on specific theoretical perspectives. However, its stated values show influences from both attachment theory and constructivist theory. Additionally, its emphasis on the competent learner and environment as teacher complement well the Montessori, Waldorf, and Reggio Emilia approaches to early childhood education. The seven basic principles of the RIE approach are (1) trusting the child as an initiator of learning and as an explorer, (2) providing an enriching environment that is safe yet challenges the infant and stimulates him or her cognitively, (3) providing time for uninterrupted play, (4) allowing infants the time and freedom to interact with other infants, (5) involving the child as an active participant in all caregiving activities and routines, (6) keen observation of the infant to get to know his or her unique needs, and (7) setting clear and consistent limits for expectations in terms of guidance and discipline.

Current Issues

Formal discussion of infant and toddler programming does not come without controversy or concern over definitions. While the term *programming* is used here, another common term used for this is *curriculum*. There is hesitation by some to use the term curriculum for infants and toddlers as it

suggests an approach to teaching and learning that is developmentally inappropriate for this age group. While the term curriculum itself does not imply the programming is inappropriate, the controversy exists due to the implications of that term and the fear that attempts at “curriculum” for infants and toddlers may look too much like curriculum more appropriate for older children. Calls for increased focus on school readiness have fueled these fears in recent years.

Abundant energy in education is currently focused on overcoming current perceived obstacles to school readiness, such as limited curriculum alignment between early childhood programs and elementary school programs. Thus, in response, many states are developing early learning guidelines for infants and toddlers as well as pre-school-age children that align with state grade-level standards to improve school readiness. The standards are useful tools but can be confusing in terms of implementation through infant and toddler programming if not tied back explicitly to the unique learning needs of infants and toddlers.

While some of the models described earlier are more structured, others are more theoretical, offering more practical interpretation and flexibility to practitioners. And it is important to note that while there may be differences in terminology and structure to the approaches described in this entry, the core tenets in each are fairly similar, and they all align with the previously described critical needs for infants and toddlers: developing a secure attachment to a primary caregiver, ability to assert autonomy while maintaining connectedness to a caregiver, exploration of the environment, and family involvement and partnership with care providers.

INFANT ROOMS

Infant rooms are spaces set up and purposely planned for the care and education of children from about 6 weeks of age to about 12 to 15 months. Infants are sometimes included in multiage groups with 1- and 2-year-olds. Infant rooms are found in full- and part-time group care settings including family childcare homes, community childcare centers, nursery and preschool programs, childcare ministries, and many community programs supporting families such as in YMCAs and family resource centers, as well to those that provide care during religious services in churches, synagogues, and mosques. High-quality care for infants in groups requires specialized expertise from a professional. Although infants are highly capable in communicating wishes and needs, it takes a skilled caregiver to understand these communications and respond appropriately. The proficient infant caregiver should be knowledgeable about the rapid

development that unfolds during infancy and understand how best to support it, and be willing to partner with families in all important decisions related to their infant's care, development, and learning.

This entry discusses group care policies, environments, and practices in infant rooms. Research supports policies and practices that promote strong, trusting relationships and environments that engage infants in interesting, meaningful play experiences.

Guiding Principles

There is no “one-size-fits-all” prescription for practice in infant rooms; many positive, respectful, relationship-based program models exist and are used for infant rooms. Regardless of what model is employed in a program, professional caregivers of infants base their actions on their own critically examined beliefs, based in reason and sound ethical and moral principles. Developmentally appropriate practice (DAP) articulates a philosophical viewpoint around which caregivers can think about how infants grow, learn, and develop, providing seven principles specifically for the period from birth to 3 years. DAP does not prescribe a model but provides a reflection point for caregivers to consider as they plan, implement, and assess work. The principles are as follows:

1. Understand there are multiple influences on development (e.g., access to health care, literacy level of family members, community resources), and growth and development must be viewed holistically, considering all domains of development (physical health and growth, cognitive development, perceptual development, small and large muscle development, social development, emotional development, and the infant's communication abilities) simultaneously.
2. Welcome all infants and their families regardless of beliefs, circumstances, needs, languages, and communication styles.
3. Enter into full partnership with families in supporting their infants, respecting families as

partners, not as clients or customers, honoring and respecting the decisions they make about their infants.

4. Be culturally responsive by being mindful of all messages conveyed to infants and their families, acting deliberately to support every infant's sense of self, including family and cultural bonds.
5. Respect infants' rights as full participants by respecting their needs and preferences, allowing choice, and supporting their overall well-being in their current daily lives as well as in preparation for the future.
6. Create and maintain a positive emotional climate, investing in all adult and child relationships with, between, and surrounding infants.
7. Engage in sensitively responsive care by remaining mindful, in the moment when communicating with infants, respond in a timely fashion to expressed needs, and "take it slow" and spend time with infants during important caregiving moments (e.g., diaper changing, feeding, rocking to sleep) and during playtime.

Caregivers need to be aware of physical/structural considerations shown to be important in infant rooms. State licensing regulations specify minimum size for infant rooms, and health and safety recommendations mandate factors such as required spacing between cribs, whether food can be prepared on site or off, records that must be maintained, and fire codes. Recommendations for group sizes and the ratio of caregiver to infants come from the field of early childhood education and have remained consistent in the United States for the past 20 years. The recommended ratio for a room with only infants is one adult for every three or four infants, and the recommended group size for infant rooms is eight or nine infants total.

Supporting Development

In infancy, the primary knowledge base comes from research in child growth and development. Skill is needed for group care providers to support

the individual needs of each infant within their infant rooms in which the developmental achievements of the first year occur at varying rates among individual infants. Developmentally, infants are working on issues of security, the need to explore, and the building of a sense of self as separate from and in relation to other people and objects in the world around them. Security is paramount for infants who need to feel they can trust their needs will be met in a timely and predictable fashion by a respectful, loving adult. The practice of assigning "primary" or "key" caregivers in infant rooms, based on the research of secondary attachment, is implemented to build a sense of security. One caregiver becomes principally, but not exclusively, responsible for a small number of infants within the group, with the goal of forming a particularly secure attachment relationship with those in that smaller group.

Infants learn about themselves and the world through exploration that occurs through the engagement of all of their senses and by moving their bodies through space. Life in the infant room must provide them experiences that allow them to see, hear, taste, touch, and smell interesting, new, and different things; and encourage them to use small and large muscles to grasp, clap, reach, slap, drop, push, pull, bang, roll, and climb, and clamber around, under, over, and through all available surfaces (indoors and outside). Materials and toys should be available that are sufficiently interesting that challenge, yet do not frustrate infants, and facilitate the development of the understanding of basic concepts such as object permanence and cause and effect.

Most important is making sure infants develop and maintain a healthy sense of self in terms of feeling they and their families are valued and respected. Infants learn important messages about caring for others and that they themselves are persons worthy of care by the way they are cared for in infant rooms.

INFANT SIGNING

Infant signing is the intentional use of specific gestures to promote bidirectional communication with preverbal children, primarily those with typical hearing. It is used as an educational tool in early childhood education settings, and as a parenting practice. It is built on children's natural tendencies to communicate with their hands prior to oral words. Infant signing promotes children's early language development, gives children a way to actively participate in care routines and behavior regulation, reduces frustration of children and caregivers, and promotes caregivers' responsiveness to children's cues.

Bridging the Infant/Toddler Language Gap

Infant signing is a supplemental and temporary communication tool used with children for whom communication is currently a challenge. This includes both typically developing preverbal children and those with communication delays. Because receptive language (comprehension) develops prior to expressive language (production), around their first birthday preverbal children begin to have specific thoughts and desires but do not have the words to communicate their increasingly complex interests, intentions, and other internal states. This language gap often results in frustration for both children and caregivers. Infant signs bridge this communication gap because infants and toddlers can use gestures—with their hands, head, and torso—to represent ideas symbolically and communicate their ideas explicitly.

Building on Natural Communication Behavior

A series of studies by Linda Acredolo and Susan Goodwyn revealed that typically developing preverbal children invent and use a few signs—or symbolic gestures—between 12 and 17 months old, and can learn many more if signs are modeled for them. Children who are not intentionally

exposed to infant signing typically invent four or five symbolic gestures on their own during the receptive–expressive language gap, just before the spurt in oral word learning. Child-invented symbolic gestures are usually “iconic” because they represent either the action performed *by* an object (flapping arms to represent bird) or actions performed *on* an object (petting motion to represent cat); they are defined as “symbolic” if they (a) are consistently used to refer to the same concept, (b) are generalized beyond the situation in which they were first learned (e.g., using a sniffing action first to refer to the rosebush in the backyard, then using it with pictures of flowers in a catalog), and (c) can represent the referent concept in its absence. Children use these invented symbolic gestures to make requests, draw caregivers’ attention to their specific interests, and elicit responses from adults. Though symbolic gesturing naturally occurs around 1 year, if infant signs are modeled consistently prior to this age, infants begin to learn them as early as 8 or 9 months. In this context, infants are capable of learning signs for many different concepts; studies have documented infant sign vocabularies of more than 60 signs, though the average is likely between 20 and 30.

Distinct From Sign Language

The specific forms of many of the infant signs taught in popular infant signing curricula come from American Sign Language, though they are often simplified to accommodate infants’ limited fine motor skills. However, the practice of infant signing is distinct from using a signed language because infant signing (a) does not involve a grammatical structure, (b) does not have a standard set of signs that have the same form and meaning, (c) is used as a supplement to oral words, and (d) is used only temporarily until children can communicate fluently with spoken language. Instead, infant signs belong to the category of communication behaviors called symbolic gestures, a type of gesture that children typically invent and use to communicate prior to oral words. The relationships of infant signs to other categories of gesture are depicted and defined in Figure 1.

Supporting Children’s Relationships and Development

Infant signing became a popular parenting and early childhood education practice after research showed that encouraging infants to use symbolic gestures promoted their language development throughout early childhood, and enhanced adult–child relationships and interactions. Some parents, educators, and interventionists fear that use of infant signs will slow oral language development because it provides children with an alternate means of communication. There is no evidence of this. Though some studies find no effect on oral language, there are no studies that find detrimental effects on language. Instead, there is evidence from experimental and quasi-experimental research that infant signing promotes oral language development as well as the qualities of adult–child interactions that promote children’s language and social skills. The practice of infant signing is consistently endorsed by parents who have used it, and by the American Academy of Pediatrics.

Guidelines for Infant Signing

- Begin modeling infant signs by the time children start using other gestures (e.g., pointing, waving), typically 9 to 11 months
- Teach infant signs that motivate children, tailored to children’s interests
- Embed infant signs in everyday routines and interactions
- Model infant signs consistently, whenever the concepts naturally occur
- Use infant signs with oral words so children connect words and signs together
- Respond to all child communication attempts, regardless of whether or how they perform a sign

Figure 1 Concept Map of Infant Signing and the Other Communicative Behaviors to Which It Is Related

Gesture:	Body movement that expresses some meaning.
Communicative Gesture:	Body movement, often with hand or head, that communicates meaning, in place of or accompanying speech. Common communicative gestures in early childhood include pointing, showing an object, and waving.
Symbolic Gesture:	Gesture that consistently represents a specific referent (object or concept) in its absence.
Iconic Gesture:	Gesture that mimics the form or function of its referent.
Infant Sign:	Gesture used by infants and caregivers to communicate a specific concept; often learned in one context or routine, then generalized to others; typically capable of representing a referent in its absence; most often iconic.

INFANT–PARENT RELATIONSHIPS

Infant–parent relationships encompass the connections between the youngest of children and their primary caregivers, including biological mothers and fathers, foster and adoptive parents, and others assuming the “parental” role. Infant–parent relationships are recognized as being of utmost significance because they serve as the

immediate context for early development. This entry provides an overview of infant–parent relationships and discusses relevant theoretical perspectives, research, and intervention, with special attention to how the construct pertains to early childhood education.

Overview

Researchers, practitioners, and policy makers increasingly emphasize the early years as foundational for later development. Infancy is characterized by a high level of brain plasticity and rapid brain development that has lasting implications for brain structure organization. Consequently, infants are especially sensitive to environmental influences. Whereas appropriate stimulation during infancy supports optimal brain development, negative experiences may be particularly detrimental.

Since infants are entirely dependent on caregivers, the significance of the child–parent relationship as a context for development is magnified during infancy. Parental behaviors vary in the degree to which they are sensitive and responsive, support learning, and encourage autonomy. The quality of interactions may directly support, or undermine, children’s short- and long-term trajectories in the domains of cognitive, language, and social-emotional development.

Theory

Developmental theories serve as the lenses through which infant–parent relationships are examined. Two especially relevant theories are described here.

Bioecological systems theory, developed by Urie Bronfenbrenner, posits that individuals develop within multilayered systems of interconnected relationships. The *microsystem*, the innermost layer of the environment, consists of the individual’s immediate surroundings, including relationships with immediate family and early childhood professionals (i.e., child care providers). Within this framework, infant–parent relationship quality is recognized to be bidirectional; parents influence their infants’ behavior, but infants, with their own sets of biological predispositions and socially

influenced characteristics, also differentially evoke responses from their parents.

While the microsystem serves as the most visible context for infants’ development, there are complex interactions with the outer system layers (*mesosystem*, *exosystem*, *macrosystem*, and the temporal dimension, *chronosystem*) that exert indirect influences. Especially pertinent to the focus of this volume, the quality of interactions *between* immediate family members and early childhood professionals, at the *mesosystem* layer, may impact infant development.

Ethological attachment theory, based on the joint work of John Bowlby and Mary Ainsworth, explains infant–parent relationships in terms of their evolutionary function. A basic premise is that infants are born equipped with behavioral repertoires that encourage close proximity to the mother, therefore providing protection from danger and promoting potential of survival to sexual maturity and reproduction, while still allowing for exploration and mastery of the environment. Attachment theory asserts that parenting contributes to predicting infant–parent relationship quality and infants’ willingness to use the parent as a “secure base” from which to explore the wider world. This relationship quality is also proposed to provide a framework (i.e., “internal working model”) for establishing other relationships.

Research

Major challenges in the study of infant–parent relationships include that the research literature has historically focused primarily on mothers and over-represents participants who are White U.S. Americans of European descent, middle-class, and from traditionally structured families. This warrants caution in generalizing the theories and findings to more diverse populations. Some have even questioned the cross-cultural validity of the basic assumptions of the widely utilized attachment theoretical framework.

However, more recent research sheds light on the construct of infant–parent relationships among diverse populations. There has been increased interest in infant–father relationships, including

among nonresident fathers, and on relationships between infants and their foster and adoptive parents. Research has also focused on better understanding parenting of infants from families who are diverse in terms of socioeconomic status, culture, and family structure.

Research results pertinent to infant–parent relationships include the following:

- Cultural background influences parenting beliefs and practices, and should be considered when studying infant–parent relationships.
- Demographic risk factors, such as poverty, poor mental health, and adolescent parenthood, can compromise parents' abilities to consistently engage in the high-quality interactions that best support optimal child development through infant–parent relationships.
- Enrollment in child care does not compromise the opportunity to form secure infant–mother attachment relationships.

Interventions

Since infant–parent relationships are viewed as vehicles to optimal developmental outcomes, early interventions designed to support children's development increasingly involve families and target infant–parent interactions. Carl Dunst, Carol Trivette, and colleagues have underscored the strengths of family systems intervention practices that emphasize respect for the roles and contributions of parents.

Susan Sheridan, Lisa Knoche, Carolyn Pope Edwards, and colleagues have developed and demonstrated the efficacy of a strengths-based, relationship-focused, parent engagement intervention called Getting Ready for promoting positive parenting and child outcomes among families with developmentally at-risk children ages birth through 5 years. Early childhood professionals participate in training and ongoing coaching to support integration of Getting Ready strategies into their practice. They focus on enhancing the qualities of the *parent–child* and *parent–professional* relationships, all in support of children's development.

INITIATIVE AND INDUSTRY

The life span is commonly divided into developmental stages to enable us to understand the specific needs and challenges and the unfolding of capabilities and competencies of children aligned with each stage. Early childhood, sometimes referred to as the preschool years, is designated as the period from infancy to the age of 5 or 6. The developmental period that follows is labeled middle to late childhood, extending over 6 to 11 years and approximating the primary school years, according to John Santrock.

Extending the work of Sigmund Freud, Erik Erikson conceptualized eight epigenetic psychosocial stages of development that individuals progress through during the life course, four of these encapsulating infancy to late childhood. At each of these stages, the individual is presented with a developmental task that entails a crisis or turning point resolution of which enhances healthy personality development. Erikson's first psychosocial stage, *trust versus mistrust* (0–1 year), provides the foundation of trust and security on which subsequent stages, *autonomy versus shame and doubt* (1–3 years), *initiative versus guilt* (3–5 years), and *industry versus inferiority* (6–11 years), are built. The latter two stages are the focus of this entry.

Initiative Versus Guilt

The third developmental crisis described by Erikson, initiative versus guilt, coincides with the preschool years. During this period, preschoolers attempt to explore their environments and are involved actively in taking on life tasks. Such efforts may be encouraged by parents fostering the child's initiative. As children engage with the wider social world, they are faced with demands for purposeful and controlled behavior. When inappropriate behavior is responded to harshly, feelings of guilt and anxiety may arise. Parental restriction of inappropriate behaviors triggers the child's feelings of personal responsibility and guilt. Optimum personality development is perceived to grow out of this balance between spontaneous initiative and its inhibition as a result of guilt and fear of reprisal, according to Erikson and researchers such as Janet Belsky and Candida C. Peterson.

Children strive to be persons in their own right. They exhibit abundant energy, and with enhanced motor, cognitive, language, and social skills they display initiative and move confidently into the social world. Their initiative and enthusiasm may bring them not only rewards but also guilt, which lowers self-esteem. There may also be a tendency to confuse effort and ability and display optimism about their abilities.

Many changes characterize young children's socioemotional development in this stage of early childhood. Their developing minds and social experiences produce remarkable advances in the development of their self, their emotional maturity, moral understanding, and gender awareness. In Erikson's portrayal of early childhood, the child has begun to develop self-understanding and self-recognition. Children are able to represent themselves in terms of physical attributes, material possessions, and physical activities. Later in this stage, at about 4 to 5 years, they display a more sophisticated self-understanding and begin to refer to their personal traits and emotions in their self-descriptions.

The child's self-concept begins to emerge in early childhood. Children begin to incorporate into their self-concept an awareness of how others see them, tending to accept the judgment of adults. The current research on social awareness in early childhood, for example, by Jeremy I. M. Carpendale and Charlie Lewis, indicates that children in this stage show an increasing ability to understand others.

With respect to cognitive development in early childhood, children's thinking and language skills develop significantly. Their vocabulary expands rapidly as they interact with parents, siblings, peers, and child care providers. They are also mastering a number of skills related to school readiness. Much of the theorizing on children's cognitive development comes from Jean Piaget, who maintained that children progress through a series of sequential stages in their thinking that corresponds to the *preoperational stage*. The preoperational stage is divided into the preconceptual period, 2 to 4 years, and the intuitive period, 4 to 7 years.

At the preoperational stage, children's thinking is said to be centered on their own perspective, reflecting *egocentrism*, an inability to perceive that another person's thoughts or feelings might be different from one's own. Piaget's work also highlighted the thinking pattern of *animism*, a tendency to assign attributes of living things to inanimate objects, referred to as "animistic thinking." Piaget's cognitive theory further notes the development of symbolic thought and language in preschoolers.

Preschoolers' new skills in thinking are reflected through symbolic or pretend play, according to researcher Mildred Parten. The play of preschool children is more imaginative and complex than that of toddlers. The parallel play characteristic of toddlers is replaced by more social interaction in cooperative play. Preschoolers learn rules and rituals and begin to take roles in different play scenarios and problem-solving situations. Gender-segregated and gender-stereotyped play unfolds as children tend to model behaviors of their sex, according to Eleanor E. Maccoby. Preschool play provides opportunities for exploring social roles, expressing fantasies and negative impulses, and practicing emerging cognitive skills including cause-and-effect thinking and perspective taking, state Jennifer Connolly and Anna-Beth Doyle.

As their symbolic representational skills advance, children develop language in the preoperational period, enabling them to communicate with others. In terms of moral development, there is gradual movement from reliance on outside approval to a more internalized sense of values derived from family and culture. The child gradually develops super-ego or a conscience that imposes standards for judging his or her behavior, and provides pathways to self-esteem based on self-approval.

The attachment relationship established in infancy continues to be significant for the preschool child. A secure attachment enables the child to experience the attachment figure as a secure base, according to John Bowlby, during the preschool years that often marks their initial separation from parents. As they make the transition to kin carers, play groups, child care, or preschool, preschoolers begin to learn to manage that separation.

During the preschool years, children, while embedded in the family with primary relationships with parents and siblings, begin to develop the capacity to relate to others in empathic ways. In the social and emotional domain, the key challenge for the preschool child is establishing friendships and playing cooperatively with peers. These relationships enhance their social skills, prosocial behaviors, and emotional regulation and enable development of skills in perspective-taking, sharing,

and cooperating, states Judy Dunn. Children at this stage are limited in their capacity to make judgments about right and wrong, being at the stage of "heteronomous morality" characterized by a one-sided view of right and wrong, based on expectations of parental figures, according to Elizabeth Fernandez.

Thus, early childhood represents a period in the life course when the child enters the larger social environment and becomes exposed to a wide range of adults and peers. The preschool-age child develops skills and competencies, especially through taking initiative in play activities that are crucial to the subsequent stage of middle childhood and significant in terms of later school readiness.

Industry Versus Inferiority

Erikson's fourth stage of development, industry versus inferiority, aligns with middle and late childhood, approximately 6 to 11 years. Erikson argues that through a process of identification children aspire to be like their parents. Erikson characterizes this process as the crisis of industry versus inferiority. The major psychosocial task of middle childhood is industry, the focus being on effort and achievement, and preoccupation with the ability to achieve good work. Children who are convinced of their abilities and whose competence is acknowledged by others develop confidence and positive self-regard. When children lack a feeling of competence and belief in their skills, they are likely to gravitate to the opposite state to industry, referred to as inferiority. The child is then vulnerable to developing feelings of incompetence, according to Michele Hoffnang and colleagues.

During this developmental stage, a pervasive theme is the child's sense of industry and curiosity about how things work. It is a period when children invest energy and enthusiasm in mastering intellectual, social, and physical skills. Encouragement of their creative efforts and problem solving increases their sense of industry. When such efforts are disparaged or discouraged by parents, children are likely to develop a sense of inferiority.

In the context of school, children in this age band are often engaged in competitive academic pursuits that engender feelings of superiority and inferiority. Involvement in competitive sports and the creative arts may further enhance children's capabilities and sense of achievement. The polarities inherent in this stage entail the pride and joy of accomplishment and the sense of inferiority that is a consequence of unfavorable comparison with the outcomes of peers. As a result of comparative evaluations of their performance with that of other children they develop feelings of relative superiority or inferiority with implications for their self-esteem and self-worth. It is also noted, by Susan Harter, that these realistic self-perceptions account for a decline in self-esteem during the primary school years. Self-worth and self-image (self-esteem) are perceived to be strongly linked to initiative and moderately to school performance, according to Harter and other researchers, such as Belsky and Peterson.

At mid-childhood, children show evidence of being able to evaluate their abilities and aspirations in relation to their peers, and where such evaluations are reality based their self-esteem is relatively high, according to Peterson. Scholastic performance, behavioral conduct, peer likeability, sporting skills, and physical appearance are five areas from which school-age children derive their self-esteem, states Harter. A balance is achieved with a dual focus on opportunities to display their individualistic competencies and avenues to participate in team endeavors that foster cooperation and collaboration and provide pathways to collective achievement.

Erikson maintains that most children in this period experience a mixture of self-confidence and fear of inferiority as they approach the end of middle childhood. Resolution of this crisis enhances children's motivation to achieve particular standards of excellence and optimism about their abilities. During middle childhood, focus of their learning shifts to a performance orientation that is reinforced by others' responses to their achievement. Erikson's conceptualization has influenced the development of achievement motivation approaches in educating school-age children. Self-efficacy, the belief that one

can master a situation and produce positive outcomes, is considered to be a critical factor in children's school achievement. School serves as an important context in this regard as committed teachers and positive environments reinforce children's sense of industry.

A number of contextual factors may impinge on children's developmental outcomes in the early years. When children experience vulnerabilities from the trauma of abuse and neglect, poor health, or persistent poverty, developmental outcomes may be compromised. Particular children, for example, those who have below-average intelligence or are less proficient in the language of instruction, may experience vulnerability as they fall behind in academic efforts and develop a sense of inferiority. Similarly, poverty, socioeconomic disadvantage, and ethnic status may pose barriers to learning at school. Growing up in different family configurations such as single-parent, blended, and extended families may pose particular challenges or opportunities for children at this stage. When children experience disadvantage from the trauma of abuse and neglect, domestic violence, bullying, poor health, or persistent poverty, it is likely a sense of vulnerability may continue into adolescence.

In middle to late childhood, children advance in self-understanding and capacity for social comparison and social understanding. This period is marked by changes in children's sense of self, including an ability to differentiate their thoughts and feelings from others. In terms of emotional development, children display increased and more sophisticated understanding of emotions of pride and shame and an ability to suppress negative emotions and redirect their feelings. As children progress into late childhood, they are able to use various coping strategies to deal with stress. Children appear to be able to make moral judgments and in comprehending right from wrong are able to evaluate their behaviors and motives. Most develop a sense of positive self-regard, which fosters resilience in challenging situations.

During the primary school years, peers are influential to children's psychological growth, affording opportunities for acceptance and approval. Peers

provide opportunities to form relationships of equality with individuals outside the family, enabling them to deal with perspectives other than their own and overcome their egocentrism. Similarly, siblings exert their influence through the learning that occurs from imitation and negotiating sibling conflict, observes L. Alan Sroufe.

Prosocial behavior such as caring and sharing, motivated by empathy, become more prominent during the school years. During this period children comprehend ideas of fairness and by late childhood can relate to notions of equity for other children with special needs.

With respect to cognitive development, school-age children develop *concrete operational thinking*, as described by Jean Piaget, mastering mental activities concerned with observable objects and events. They attain the skill of *conservation* (an appreciation that properties of mass and length remain unchanged despite changes in appearance) and other new skills including *seriation* (appreciation of size, weight, and length), *categorization* (flexible thinking about classifying objects/individuals), and *spatial relations* (ability to comprehend spatial relations of their daily environment). Piaget's conceptual work on cognition and children's thought processes underpin approaches to education in the primary years.

This period is also significant in terms of gender identity. Important changes in sex role socialization occur between mid-childhood and adolescence. While gender segregation is less pronounced in the preschool years, it is more evident in middle to late childhood. Cultural identity is also of significance for children in that children may be exposed to conflicting cultures, most obviously children from ethnic minority families and those who are refugees. For many of these children, there will be the challenging need to understand both social worlds, learn to operate in both, and incorporate both identities.

Conclusion

It is important to note that each developmental stage is embedded in and builds on previous stages,

besides being enmeshed with the life span of others. While recognizing each stage as a discrete entity, treating each as mutually exclusive is limiting.

While the developmental theories of Erikson and Piaget reviewed portray a universality of children's needs and developmental trajectories, it should be noted children are individual and care is to be taken not to homogenize them. Young children come from diverse cultures separated by gender and categorized by health status and social class, and they have constantly changing needs based on age. Matthew Colton and colleagues note that the Western bases of child development norms carry with them a power differential that is aligned with White, middle-class baselines.

Piaget's theories have been challenged in relation to his estimates of children's competencies at different developmental stages, and the need to recognize the impact of training, education, and culture on their capacity to think and reason at different and higher levels. Lev Vygotsky's influential theory, the zone of proximal development, and Urie Bronfenbrenner's ecological theory maintain that development is context-specific and must be understood in the context of the social interactions and dialogues that take place between a child, parents, teachers, and other representatives of the culture. Parents, peers, teachers, and mentors often provide scaffolding to strengthen and extend a child's capabilities.

INQUIRY

Early childhood education has long been synonymous with approaches that are integrative of children's backgrounds, home lives, and existing knowledge—the process by which the field mixes together a set of related learning concepts (such as science, math, and literacy) into one congruent arrangement of lessons. However, it has also been tradition that many early educators approach the classroom with didactic arrangements of topics, such as colors one week and shapes the next. In some ways this traditional approach to learning is “easier.” The teacher plans the lessons and sets up the environment based on his or her understanding of child development and the developmental needs of his or her classrooms. While the teacher perspective is needed, it is also important to listen to the curiosities (in what children seem to be interested) of children in guiding what a teacher implements in the classroom. More importantly, according to Lynn Hill, Andrew Stremmel, and Victoria Fu, it becomes necessary to find a curricular approach to make the learning most understandable and meaningful to the children: inquiry-based methods.

Hands-on activities such as role play, dramatic play, pretend play, and imaginative play all help to make concepts leap off the pages of a lesson plan and become integrated into the children's existing schemes as the play scenarios relate to their lives. According to Hill, Stremmel, and Fu, using methods that tap into children's existing knowledge enhances their learning by giving them a point of reference with which to make associations. Inquiry-based methods are becoming more widely accepted in today's early learning classroom.

Classroom Content Learning

Historically, most classroom content learning is approached within arrangements of topics in

curriculum, or thematic planning. Typically, these themed lessons are developmentally based, teacher-created modules, that may or may not relate to each other and typically move at a fevered pace; they might involve learning about community helpers one week and the ocean the next. Far too often this type of planning misses two target ideals: acknowledging children as the protagonist in their learning and integration of children's existing knowledge into the lessons.

Thematic planning leaves a gap in knowledge and often exposes children only to surface content, including stereotypical representations of race and ethnicity. One way to move from a historically static type of learning into a more dynamic type of learning would be to consider the benefits of inquiry methods. More importantly, a more dynamic approach will allow the teacher to embrace whatever societal trends pervade the curriculum; it will move with the ebb and flow of the variety of topics considered relevant at the time.

Progressive Education and Inquiry

There is an increasing argument among some school district leaders and state education officials that a standards-based, prepackaged curriculum is more beneficial to children's long-term learning and boosts children's social abilities. It undoubtedly eases the burden on teachers' time in planning. However, it is not in the best interests of the children to deliver curriculum that has not been developed to meet their individual needs or the needs of specific classrooms.

In earlier times, educators and philosophers such as John Locke (1632–1704), Jean-Jacques Rousseau (1712–1778), and Johann Heinrich Pestalozzi (1746–1827) professed that educators of young children should use child-centered practices. After studying the Swiss educator Pestalozzi's fervor for educating every child with the skills he or she needs to be successful in life, Friedrich Froebel began what developed into our modern-day kindergarten. In the text *Reinventing Kindergarten*, Norm Brosterman suggests that Froebel believed children had innate curiosities

that drove their desire to learn and it was the educator's job to support that curiosity.

John Dewey was a pioneer in his time for seeing children as protagonists in learning. He valued their input and past experiences as evidence of cognitive knowledge. This began a shift from teachers being seen as filling an empty vessel of a child to teachers who worked in collaboration with the child to build (co-construct) knowledge. Dewey's philosophies are ever prevalent for those who attempt to move to a social-constructivist, inquiry-based methodology.

Dewey continued to profess the appropriateness of child-centered education as early education moved into the 20th century. His pedagogical approach of negotiated curriculum gave us the ability to trust that children can be active participants in the planning and delivery of content. What Dewey could not have foreseen was how the accountability movement and in particular the No Child Left Behind Act of 2001 would greatly change the landscape of approaches in early education. A new focus on mastery learning and the need for performance data moved many classrooms to leave behind the original intent under which early education was founded.

While there is no one program that will fit the needs of all children, it seems most compelling to place children in programs that look toward the past for guidance—to Pestalozzi, Froebel, and Dewey—and return to the key themes of what we know to be appropriate for young children: early learning environments based on emergent curriculum, hands-on materials, and most importantly to respect that innate drive that guides children in the learning process. With the world of education still grappling with the movement toward scientific-based educational research, as a byproduct of No Child Left Behind, it is important to ask important questions when it comes to educating societies' youngest, most malleable children.

The crux of any good ECE/SE program relies on the faculty understanding of age and individual appropriateness when setting up the learning environment and providing instruction. In an inquiry approach, the needs of the developing child drive

the delivery of content. The aim is to help teachers think outside of the box that is considered “traditional” educational practices—thinking of ways to change curriculum, methods, and environments to support different ways of learning. Of course curriculum alone does not an effective early education program make. It is vital to be a reflective and informed decision maker when considering providing services for all children, using best practices. Susan Bredekamp defines best practices as techniques or methods that, through experience and research, have been proven to yield the most desired results.

A teacher can be frustrated to receive a child in his or her classroom when it is evident that in the previous classroom the child’s particular needs were overlooked, and that instead the child’s skills or behaviors were viewed according to whether they were “within the range of typical development” as viewed strictly from a textbook perspective. Certainly observing and identifying needs is of the utmost importance for the early childhood classroom teacher. Combining those observations with knowledge of whole child development, family structure, and environment will provide the best picture of the child’s needs and abilities.

Planning an Inquiry-Based Classroom

The most difficult part of starting an investigation is giving up tight teacher control of the planning and delivery of the curriculum. It is now simply not enough to survey the class for needs without researching ways to set up the environment and curriculum to sustain good questions. There must be planning and setting up more incidental learning as well as anticipating children’s questions and what to do when those questions change. Teachers must not give up so much control that the children plan and set up each part of their day with no adult attention to standards of learning and development. Having an inquiry project or investigation in process, with a teacher guiding the learning, always monitoring interests and conversations, and adhering to standards of learning, is a delicate process. Think of it as the teacher spinning plates on a

stick. All of the elements must be in constant motion to keep the plates from falling (making sure needs are not going unnoticed) and trying to keep the plates spinning in the same direction (listening and responding to the children’s interest and needs and ensuring the curriculum also meets standards). Effective inquiry teaching interactions are based on the reciprocal relationships between the children’s questions and teacher understanding of skills that need to be taught.

For example, a teacher may have the didactic curriculum already planned for learning colors one week and letters the next, but what happens when he or she is keenly observing children’s interest, listening to their conversations, and watching what seems to fascinate them? The proverbial light bulb goes off and he or she can return the lesson plans to capture activities and materials that support the children’s questions.

Let’s say the children in one classroom are showing a great interest in the construction project across the street from the school. Their daily conversations somehow always gravitate toward what they are seeing out the window. The teacher will now start revamping previously planned activities and begin planning lessons, activities, and questions that help children find the answer to their inquiries as well as avenues to investigate new questions, all while incorporating academic content. In this instance perhaps the teacher brings sand and bulldozers and play buildings into the sensory table to imitate the construction zone in their immediate environment. Children would be encouraged to compare and contrast sizes and shapes of the buildings in their sensory table construction area with the building in the outside construction area (math), document questions and draw and label pictures of what they see happening (literacy), and on this process goes until the questions are answered or the children’s interests change. What makes this so dynamic is that it is meaningful and interesting to the children, which makes them highly engaged in discovery.

Using daily routines, planned activities, and natural and logical consequences, a teacher can provide instruction that helps children develop in all five

domains: social, emotional, cognitive, language, and motor. Child-initiated activities are those that will hold a child's interest the longest and will be retained more often.

INQUIRY-BASED LEARNING

Inquiry-based learning is also referred to as *project learning*, or the *project approach*. In early childhood education, inquiry-based learning is often linked to the Reggio Emilia approach developed in Italy, John Dewey's theory of experiential learning, Lev Vygotsky's theory of sociocultural learning, and Jean Piaget's developmental theory. The primary aims are rooted in investigations based on authentic interests of the children, peer collaboration, critical thinking, autonomy, and documentation and communication of learned knowledge. As discussed by Diane Parker:

Inquiry is a way of looking at the world, a questioning stance we take when we seek to learn something we don't yet know. And when we are truly inquiring about something, whatever it may be, we drive ourselves to learn more and more because we are seeking answers to our own questions. (Parker, 2007, p. 1)

Early childhood education has an extended history of supporting children's discovery and inquiry through exploration of the environment, including objects, people, and places, and engaging young minds in meaningful representation of these experiences. The integrated learning from these explorations builds children's social, emotional, physical, and cognitive knowledge and motivation for learning.

Planning for this type of learning requires careful attention to the environmental setup, the intentional use of space, smaller groups, and a balance of exploration and guidance from the teacher. Children will show different levels of interest in any particular topic of study, which is why multiple investigations and multimodal approaches representing their knowledge both are critical for meeting the needs of diverse learners. Involving parents and community experts is an important part of the collaborative learning process. Hearing from experts on the topic under investigation and visiting field sites for primary experiences afford children opportunities to interact directly with those knowledgeable in the field of study.

Theory

Educational and developmental theories have influenced early childhood pedagogy. The three theories in particular mentioned earlier have impacted early learning as well as preservice training programs. Additionally, early education policy and programs in Reggio Emilia, Italy, have been models for the experiential and constructivist approaches for teaching.

Dewey's experiential learning theory is the foundation of democracy education, the progressive education movement in the early to mid-20th century. He founded the University of Chicago laboratory school, which became a model school for child-centered, experiential education. He did not prescribe curriculum but helped shape the understanding that children are autonomous human beings with curiosity that motivates them to learn by doing.

Vygotsky's sociocultural theory emphasizes learning through social interaction. Further, learning is situated in a cultural context that is integral to children's education. Pedagogy focuses attention on offering enough guidance and culturally relevant support that children can appropriate knowledge and the learning process toward autonomy. Peer and adult-child interaction and symbolic representation become central to an engaging educational environment.

Likewise, Piaget's developmental theory values social engagement, exploration, and problem solving, which lead to knowledge construction. Vygotsky and Piaget are both grounded in the social construction of knowledge. However, Piaget focuses more on the developmental stages children go through in constructing knowledge from the world surrounding them. Further, the model policy and educational settings that Reggio Emilia offers are centered around the rights of children to have engaging educational environments that support their natural curiosity and drive to learn. Inquiry and investigations, the project approach, are at the center of this model. The teacher's role is to observe children, engage their interest in multiple inquiries, document their observations, empower children to represent their learning, and enable meaningful communication of their findings.

Investigation Approach

A challenge to teachers in the investigative approach is to bridge their observations of children's interest to meaningful resources from which children will come up with questions that will further their research and knowledge acquisition. Teachers need to be prepared for three phases of an investigation. Once observed interests are identified through symbolic play, shared stories, shared experiences, and so on, teachers provide numerous resources in the classroom, including books on topics that have emerged as particularly interesting, materials to explore, opportunities for symbolic play and representation, and then determine which topic(s) to pursue in depth.

This leads to phase I, beginning the inquiry. Children generate questions, facilitated by interactions with the resources and discussions the teacher leads. With guidance children plan how they might research their questions. Children document their questions and prior knowledge in multiple ways, through multiple media. In phase II, the inquiry, children investigate further their specific questions with field visits that afford direct observations enhanced with experts in the field of study. Documentation is central to the process; children represent their learning process and new knowledge. Phase III is comprised of children sharing and celebrating their investigation and findings with others, usually culminating in multiple projects that emerged from their inquiry. This phase contributes to children's ownership of the project and ability to communicate their learning effectively and meaningfully.

Some of the tenets specific to inquiry learning are as follows:

- Children are naturally curious and are successful learners with an appropriate balance of environmental support and exploration.
- Children self-regulate best when exploring through symbolic play and representation of knowledge.
- Adults' roles include providing a rich environment with resources from which children can choose to experiment and build constructs,

observing closely each child's interest and learning, and scaffolding their representational process and outcomes.

- Attention to complex interactions among families of diverse backgrounds is critical to building successful learning communities.

Early Childhood Teacher Education and Research

Early childhood educators have long understood the need for developmentally appropriate practice for young children and the professional development of preservice and in-service teachers of young learners. Theory and research emphasize positive outcomes when educators focus on children's strengths, interests, and curiosity within cultural and familial contexts. Scholars such as Luis Moll and James Coleman provide educators with a background for partnering with diverse families while developing self-awareness regarding educators' beliefs and prejudices as well as sensitivity to various cultural routines and expectations. Reciprocity with families enables a wealth of resources and support for successful outcomes for children's inquiries for construction of knowledge.

Additionally, teacher education programs and community partners are combining efforts to research relevant higher education curriculum and meaningful internship experiences for teacher candidates. Efforts reflect also the increasing need to document children's learning that meet the Common Core State Standards. Further, portfolio assessment of teacher candidates demonstrates teacher-student engagement in the classroom facilitating children's depth of inquiry and critical thinking. Increasing attention to collaborative efforts among teacher education programs, school administrators, and teacher mentors shows promise for research and school improvement.

INTEGRATED APPROACHES

An *integrated approach* combines the education and care of young children (early childhood education and care, or ECEC) in a holistic and coherent manner in order to support families in the ongoing relationships that exist between direct and indirect services that occur within the meaningful environments and experiences of early childhood. This type of approach utilizes a network of multiple services working together as interdependent dimensions within the field of early childhood. Young children and families are provided access to services that may include social welfare, child care centers/schools, family supports/agencies, employment/vocational services, and health services.

The traditional approaches to early childhood education define the education of the child and the

care of the child as two separate sectors (i.e., state versus family) with separate responsibilities. Factors such as industrialization, changes in the family dynamic, declining birth rate, poverty, and the shrinking work force have had a negative impact on the effectiveness of traditional approaches. The separate responsibilities between family and state often result in inconsistencies in quality of care across age groups and with related transitions between and across services.

Integrated approaches to early childhood education create a shift in thinking from a selective and exclusive focus to one that is universal and inclusive. Relationships between state and family are redefined to ensure quality home care and effective access by families to quality, basic services. The rights of children become paramount so they can reach their potentials in all areas of development to include cognitive, language, social-emotional, and physical domains. Finally, families and society work collaboratively to share the responsibility of appropriate care and education of their children (i.e., a human rights model replaces family alone/society-at-large focus) to provide more capability in accommodating the diverse needs of families.

As the boundaries between the disciplines and services become interdependent, the multiple facets of socioeconomic/cultural, political, and pedagogical factors warrant a broader theoretical framework and rationale that provides a common grounding for the coordination and implementation of quality early childhood education and care. The resulting paradigm shift to a collaborative and holistic mindset has implications for both policy and program implementation.

Policy Implementation

The changes in terms of policy implementation impact the early childhood education system, administrative services and agencies, the populations and age of children receiving services, and the program budget. The comparisons between traditional and integrated approaches are described in Table 1.

Remaining Policy Considerations

Practical challenges remain with the coordination of policy implementation. For example, the definition of a unified policy that ensures dual ECEC functioning of social and educational sectors still requires refinement. The shift from traditional to integrated approaches is slow, and many aspects of the traditional approach remain firm in ECEC institutions across the globe. Different age groups receive unequal attention due to services in different systems, and this “disconnect” with the transfer of services between sectors impacts the appropriateness and ability to accommodate diverse needs. A strong public commitment is required for ECEC accessibility to support young parents especially during their child’s earliest years of life. The care for children under the age of 3 is understandably more costly because of the required high adult–child ratios, equipment and supplies, and so on. Quality is often sacrificed when cost is a factor, so public investments must be considered in order to support services and the infrastructure such as social-development projects. Lastly, appropriate training and work conditions must be provided for early childhood professionals with ongoing monitoring, data collection, research, and evaluation to ensure quality improvement and sustainability.

Program Implementation Within Integrated ECEC Approaches

The integration of early childhood education and care has implications for program implementation. The impact on service delivery, staffing, settings, pedagogical methods, and parental involvement is explained in the following sections.

Service Delivery Model. The challenge is to develop a unified system with objectives that provide for diversity of services beyond the boundaries of the traditional school system. The school-oriented (traditional) model is often limited in scope (i.e., provisions are center based, during school year, and school hours only). With a client/family-focused model, services are tailored to provide flexibility and a variety of options (e.g., center

Table 1 Policy Implementation: Traditional Versus Integrated Approaches

	<i>Traditional</i>	<i>Integrated</i>
Education System	Focus on preparation of schooling. Exclusive access to early childhood care for at-risk populations and special needs. Family has exclusive responsibility for early years (0–3 years), and state responsibility begins at age 3.	Focus is on child development. Universal access to early childhood education and care with increased state responsibility and focus on the whole child beginning at birth. Mutual partnership between family and state/society.
Administrative	Traditional split model between education and health/public welfare systems.	Unified model with coherence and coordination in objectives, funding, operating procedures, and regulation.
Target Population	Selective/Exclusive or Deficit Model. Primary focus on children and families of poverty, special needs, and other “at-risk” populations.	Universal/Inclusive or Human-Rights Model. Focus to accommodate diverse needs of all children and families (e.g., birth to age 8, pregnant women, and caregivers).
Age Range	Coverage for education and care for children 3 and older because of their “rights” to public funding. Minimal focus on birth through 3.	Expanding age range from birth to age 8 assumes a more active role in providing services at the state level, with a particular emphasis on the birth through 3 age groups.
Budget	Private funding.	Public investments in services and infrastructure; effective state involvement; quality and affordable early childhood education and care.

based/home based, full time/part time, same age/ mixed aged) for high-quality care.

Staffing. With an integrated approach to ECEC, the responsibility of child socialization shifts from a private issue to a professional responsibility. Trained staff is essential and the work force must have compatible goals and coherent program implementation. Challenges remain with budget constraints that negatively impact teacher compensation. This in turn puts welfare or lower-funded systems at risk for limited access to well-trained and qualified staff.

Settings. With integrated ECEC, the former institutional setting of a school is transformed into

spaces for children within home- and community-based environments that are respectful of the current family dynamics (e.g., working parents, smaller families, single-parent) and facilitate development of relationships between early childhood staff and families.

Pedagogical Approaches. Traditionally the care-oriented approach, where learning is the primary focus, views children as recipients of care or needing compensation for home environment deficiencies. An integrated pedagogical approach considers the whole child, and children are now seen as competent and active participants in their learning. Teacher-directed learning is replaced with child-directed learning to create a pedagogy for ECEC

that fosters a culture that protects and respects children in their own right both as individuals and as members of their communities.

Parent Involvement. Rather than limiting the rights of parents, integrating ECEC supports parents as partners in the shared responsibility of the socialization of their young children. Strong parent–staff relationships are paramount and based on open communication, trust, respect, shared knowledge, and family traditions. The ECEC settings should provide social networking for parents to form ties with other families and community members. Challenges remain, however, with ensuring mutual respect and parity of roles between all parties.

Benefits of Integrated ECEC

Integrated early childhood education and care approaches have been applied to address problems in at-risk populations with high infant/child mortality rates, young single parents, HIV/AIDS, malnutrition, poor psychosocial development, delayed development, and low school readiness.

The successful applications of integrated ECEC has brought to light the multiple benefits of using this approach: (a) providing a coherent policy to regulate funding, training, and service delivery across systems; (b) ensuring a continuity in transitions from one educational system to the next through cooperative relationships between early childhood caregivers and primary school staff; (c) broadening experiences for children and families with universal eligibility across expanded age levels; (d) facilitating multiple opportunities to reinforce learning, form new frames of reference, and increase understandings of the world; and (e) providing intentional and meaningful support for families to increase parent involvement and to enhance socialization opportunities and social networking cohesion.

INTEGRATED CURRICULUM

In early childhood education, learning focuses on the whole child and how each child makes sense of his or her world. Integrated curriculum unites concepts across subject areas, such as mathematics and social studies, through learning experiences that enhance the child's skills, knowledge, and thinking. The experiences reflect a program's goals and educational standards, and are planned to make learning meaningful and engaging. Integrated curriculum is the how, what, when, and why of a program of study, which connects subject areas and developmental domains to enhance learning.

What Is the "Whole Child"?

The whole child refers to a basic understanding of who is the primary focus in early childhood education (ECE). For children from birth through 8 years, learning occurs through each child's interaction with their environment. This interaction requires the engagement of all domains of development: physical, intellectual (cognitive), and social-emotional. Gains made in one domain spur development of concepts in the other domains. For example, when a child begins to crawl, his world enlarges, which encourages further manipulation and exploration of his environment. This manipulation and exploration lead to

the development of new concepts (intellectual development), as well as learning limits with the frustration and consequences that limits entail (social-emotional development).

In primary, elementary, and secondary education, learning has been viewed as primarily a cognitive activity. Physical development and social-emotional development were considered unimportant or tangential to academic achievement. Life skills and preparation to be a productive member of society, which underpin progressive education, were displaced by emphasis on academics. Research in how humans learn has brought new awareness of the need to consider the whole child. In 2007, the Association for Supervision and Curriculum Development (ASCD) launched a Whole Child Initiative, which stresses the return to the broader purposes of education for teachers and communities.

Importance of Integrated Curriculum

Integrated curriculum relates to early childhood education in several significant ways. First, integrated curriculum in early childhood has a theoretical base in the nature of how children learn. Constructivist theory, as described by Jean Piaget, holds that the learner builds new knowledge internally on a base of previous knowledge and through interaction with his or her environment. Sociocultural theory, Lev Vygotsky's view of intellectual development, expands the constructivist theory. Proponents of this theory believe that language, social interaction, and culture highly influence learning. Integrated curriculum uses the young child's natural need to explore, interact with others, and construct knowledge.

Second, within integrated curriculum concepts are interrelated. Natural relationships that exist between phenomena make an integrated curriculum more cohesive and relevant to the learner and teacher. Based on the knowledge of the various disciplines at that time, Aristotle advocated teaching that made relationships clear between the disciplines. In 2009, the National Association for the Education of Young Children (NAEYC) issued a revised version of its position statement, *Developmentally Appropriate Practice in Early Childhood Education*

Programs Serving Children From Birth Through Age 8. One of the key messages of that position paper states that comprehensive, effective curriculum for young children needs to provide learning experiences that are more integrated and aligned than in the past.

Third, integrated curriculum supports and enhances inclusion. Inclusion refers to the educational practice of placing children with special needs in the least restrictive learning environment, which is often the regular classroom. Early childhood educators believe that all children can learn in their own way and at their own pace. When integrated curriculum design is used, children of all abilities and skills can participate and learn. Positive outcomes may occur in the academic domain and more importantly in the social-emotional domain.

Benefits of Integrated Curriculum

The benefits of integrated curriculum are closely aligned with the importance of integrated curriculum in early childhood. Integrated curriculum enhances the formation of concepts, develops a wide range of skills, and expands critical thinking. In early childhood, an integrated curriculum starts the child on a journey of lifelong learning. In addition, research has shown that integrated curriculum

- improves student motivation and discipline within the classroom;
- promotes and enhances social interaction and learning from and with peers; and
- helps all students academically in the primary grades and above.

How Does Integrated Curriculum Work?

The implementation of an integrated curriculum is varied, as a review of the literature reveals. Discussion of integrated curriculum sometimes focuses on who or what drives the curriculum and a continuum of teacher-directed to child-directed approaches is suggested. Some writers view integrated curriculum as a curriculum design approach in which the content to be taught is reorganized into themes to connect the disciplines or subjects,

that is, as a multidisciplinary approach. A second approach uses common concepts from several subjects as an organizing structure and is referred to as interdisciplinary. Within a third approach, the discipline or subject knowledge is stressed less than learning important life skills within a real-life context, which is called transdisciplinary. Each provides direction to improve teaching and learning, and demonstrates changes in teacher attitudes/dispositions toward shared responsibility and innovation. These three approaches to integrated curriculum differ in some specific ways: first, organization of the experiences; second, the role of the teacher; third, the view of the disciplines/subjects; and fourth, the acquisition and understanding of knowledge.

Through the multidisciplinary or theme approach, traditional school subjects, such as math, science, and social studies, are organized and taught by using themes, such as winter or weather. Distinct concepts and skills significant to the discipline are taught through planned experiences, which are directly related to meeting discipline standards. The teacher's role is that of a specialist and facilitator of the process. The structure of the disciplines is viewed as the most effective way of acquiring knowledge and meeting standards. Emphasis is on giving the correct answers and using the procedures and processes of the discipline. Assessment of learning occurs through traditional testing methods such as multiple-choice questions, short answers, or demonstrations of the knowledge, process, or procedures of each discipline. Common examples of this approach include service learning programs and the use of learning centers within the classroom.

Using an interdisciplinary approach, common skills and concepts of several disciplines are the organizing structure. Thinking skills, problem solving, measurement, reading, and comprehension are examples of common skills embedded in the subject disciplines, which are used to organize the curriculum. Lessons or explorations demonstrate the common principles, which then lead to the discovery and development of other skills and concepts. In this approach knowledge is socially

constructed and allows for a number of right answers. Emphasis is on the interdisciplinary concepts and skills in both planning for learning and assessing outcomes. The teacher's role is as a facilitator and specialist within the process. The integration of science, technology, engineering, and mathematics, commonly called STEM, is an example of this approach. Some schools are enhancing the STEM integration with the inclusion of the arts, referred to as STEAM. Learners become more confident and competent in the STEM and STEAM subjects when exploring, discussing, and demonstrating the outcomes of their learning activities.

The philosophy and goals of progressive education for a democratic society, advocated by John Dewey and others, provide the basis of the transdisciplinary approach to integrated curriculum. Dewey saw the goal of education to be the preparation of the learner as a productive member of a democratic society. Student concerns and questions are the organizing structure with an emphasis on real-life situations and experiences. Knowledge is viewed as changeable, interconnected, and interdependent, leading to multiple answers. Discipline knowledge or subject knowledge is considered within the context of solving a problem, but it is not emphasized. Integrated curriculum has at its core a deepening knowledge of one's self and the world with a goal to resolve issues. Everyone is viewed as a learner—child and teacher. The transdisciplinary approach presents a paradigm shift in teaching and learning because the teacher shares responsibility for the curriculum with the students and becomes a co-learner and co-planner. James Beane and others claim that correct implementation of integrated curriculum is found in only this approach.

The Project Approach demonstrates this approach to integrated curriculum in early childhood programs. Sylvia Chard and Lilian Katz advanced this project-based approach. Their process involves three steps:

1. Children and teachers select a topic to investigate. The topic is based on children's interests, curriculum standards, and local resources. During this step of the project,

teachers find out what children know and what they would like to know about the topic. Teachers then generate a list of questions to be answered and possible ways to find the answers.

2. The teacher provides possible resources and opportunities for field work. Resources may include field trips, explorations outside of school, and opportunities to talk with individuals related to the topic. Children are placed in small groups according to their common questions and interests.
3. A culminating activity shares the results of their work with others. Children share the results of the exploration and review and evaluate their project.

Research shows the impact of positive social and emotional development to the enhancement of life skills and academic achievement. One of the strengths of integrated curriculum is its engagement of the whole child in fostering development in all domains. Central to integrated curriculum is the social interactions found in each approach. The Collaborative for Academic, Social, and Emotional Learning (CASEL) and the Center on Social and Emotional Foundations for Early Learning (CSEFEL) have produced resources and research to support social and emotional development in young children. Integrated curriculum enhances the child's skills, knowledge, and thinking in all developmental domains.

INTELLECTUAL ASSESSMENT

Intellectual assessment is a fairly sophisticated field, with tools that have been refined for over 100 years. Not all of these tools apply well to early childhood (birth to age 8), but some of them do. There are compelling reasons to assess intellectual functioning during early childhood. Two reasons that are often noted are detecting exceptionalities and allowing empirical research on intellectual development. Exceptionalities may reflect creative potentials or the potential to excel, or they may be indicative of developmental concerns, in which case the intellectual assessment is an important part of a diagnosis. In terms of research, intellectual assessment tools are especially helpful for longitudinal research, and longitudinal research may be the most powerful method for studying development.

This entry reviews the methods for intellectual assessment during early childhood. Some of the more common tests are briefly discussed, as are the pros and cons of each. Intellectual assessment during early childhood can be challenging. The

child between the ages of birth to 8 years is generally not accustomed to tests, as are older children. Attention span can be limited, as can communication. Stranger anxiety can come into play and distort the assessment. Any one of these challenges, at the extreme, can preclude the administration of a test. Even if less than extreme, each can add significantly to measurement error. Admittedly, every intellectual assessment has some measurement error. No test is perfectly reliable. Still, if there is rapport, communication is good, stranger anxiety is absent, and attention is maintained, the tests discussed in this entry can give meaningful results.

Examples of Tests

One test that was specifically designed for infants is the *Bayley Scales of Infant Development*. It focuses on psycho-motor behaviors in children between 2 and 30 months. Tasks include (a) turning to observe an object, such as a spoon, as it moves; (b) vocalizing displeasure; (c) smiling at an image reflected in a mirror; and (d) inspecting a ring (especially sustained inspection). The last of these is supposedly indicative of alertness and exploratory behavior. Observing a moving object is indicative of goal-oriented attention. Smiling is of course a social response. And vocalizing any sort of displeasure was labeled by the test author as an *extrovertive response* that may be goal centered or goal oriented. There is an addition to the Bayley Scale for children at age 12 months that adds an assessment of communication skills and “intellectual concepts.” Cognitive psychologists define concepts as clusters of information. (They have also been called schema, schemes, and scripts.) Even a 1-year-old constructs knowledge structures, or concepts. When the child has developed concepts, movement becomes more controlled and the individual is more likely to obey simple commands, and perhaps imitate. Behaviors move from reflex and stereotyped *circular reactions* to exploration. Concepts are meaningful indicators of intellectual capacity, even at 12 months.

The Infant Psychological Development Scales represent a second assessment that can be used

during infancy. These assess vocal imitation, visual permanence, visual pursuit of objects, and an understanding of causality. Importantly, this test recognizes that development is usually stage-like, and one intellectual skill must be developed before more mature skills would be expected. There are exceptions. An orderly progression from stage and skill to more mature stages and skills is not always found. Indeed, people assessing the intellectual capacity of very young individuals should recognize that there may be some instability. A lack of stability is frequently attributed to low reliability of the assessment, but in early childhood it could also be a reflection of fluctuations in behavior. Some instability must be expected when assessing the intellectual ability of very young children. Jean Piaget referred to exceptions to stage-by-stage development as *decalages*.

There are measures that focus on specific intellectual skills, such as the *Scale for Construction of Object Relations in Space*. The test manual for this scale suggests that at 2 months, an infant will probably glance from one object to another when two things are present but not side by side. One month later, the infant alternates from one object to another but more quickly. At 4 or perhaps 5 months of age an infant will attempt to grasp the object. At 7 months, the infant may demonstrate some anticipation, such as when an examiner rolls an object off of the testing surface and the infant moves his or her eyes toward the spot where the object will probably land. At 9 months, an infant is likely to take small objects, such as blocks or perhaps beads, pick them up, and drop them into an empty container, if one is at hand. Here again development is seen as progressing in a linear, stage-like fashion.

A newer test of cognitive ability was published in 1983 and is called the *Kaufman Assessment Battery for Children* (KABC). It drew from the cognitive sciences, including neuropsychology, and postulated that there are two important cognitive functions that can be assessed. One is *simultaneous processing*, and the other *sequential processing*. Simultaneous processing occurs when the individual takes various pieces of information and is able

to integrate them into one solution or one meaningful interpretation. The KABC has one task, called Magic Window, where a common object can be seen, but only a little bit at a time. The object moves behind a slit so only the part showing through the slit can be seen. But a child with good simultaneous processing skills will be able to integrate the information into a meaningful interpretation. The child will be able to name what object moved behind the slit. This integrative process may sound like something from Gestalt psychology, and as a matter of fact there is a Gestalt Closure task where some common object is presented on a card, but most of the image is missing. A child with good sequential processing skills can infer what is missing and again construct a meaningful interpretation.

Both of the tasks just described used “common objects.” That is because the KABC was predicated on the idea that simultaneous and sequential processing can operate independently of experience. The authors of the KABC were well aware that many IQ tests for older children were plagued by experiential biases. These occur when an examinee does well on a test, not because of ability per se, but because he or she had experiences that allow successful performance. There is a rebuttal to this view, namely that a person needs to have the ability to benefit from experience, in which case one could say that performance on a test that allows experience to play a role is a reflection of both ability and experience. In any case, the KABC was developed such that experience plays a very small role in simultaneous and sequential processing.

While simultaneous processing requires an all-at-once interpretation of an image, *sequential processing* is apparent in step-by-step problem solving. Hand movements test sequential processing. The examiner presents simple hand movements, one at a time, one second apart. Once the examiner is done displaying one set of movements, the child must repeat the same hand movements, in the same order. This test is not unlike “digit span” that is found on some tests for older examinees, and sequential processing may be indicative of real-life skills. Very frequently, to solve a problem correctly,

the steps in the solution must be followed in the correct order. Mathematics very frequently requires sequential processing, just to name one example.

Alan Kaufman and Nadeen Kaufman, who supervised the research team that developed the KABC, recognized that many existing measures of general intelligence, including the IQ, are potentially biased by experience. They have argued that their measures of simultaneous and sequential processing are more or less free of experience. They did include a third scale in the KABC to specifically target the impact of experience. This is the *achievement scale*, and a child will only do well on the achievement scale if he or she has had particular experiences. In a matter of speaking, it turns what is commonly known as an experiential bias on its head and attempts to quantify the impact of that experience.

The KABC can give a simultaneous processing score, a sequential processing score, and an achievement score. This results in a profile that includes both of the primary intellectual functions of the human brain, as well as an index of how much experience the individual has had and how much he or she has benefited from experience. This last point is especially important because people who trust traditional IQ tests realize that experience can play a role, but argue that the individual must be intellectually capable of benefiting from experience.

The KABC can easily be given in a standardized fashion. The materials lend themselves to consistency of administration. The examiner can easily move from task to task, and scoring and prompts and the like are discretely hidden from the examinee. Ease of consistent administration is enormously important. Without consistency and standardization, scores from different examinees or different testing periods cannot be compared. Norms would be worthless if some children received a test under one set of conditions while another child received the same test under different conditions.

Standardization is much more difficult than it sounds. It is not, for example, just a matter of using the same directions with each examinee. The tone

of the directions must be the same. The feedback must also be consistent, and this is especially difficult. Adults may be tempted to reward children who answer questions correctly more than children who do not know as many answers, but this would be unfair and represents a kind of inconsistency. Also, the hand movements task requires that the individual movements are given one each second. That too is difficult; there is a general tendency to add tempo to such things, but that could give the examinee an advantage. The tempo could provide information that facilitates the processing of the information.

For reasons such as these, intellectual assessments should be given by trained professionals. They should be given only after the tester has participated in many practice sessions and after there is certainty about the standardization of administration. There will still be measurement error, but standardized assessments minimize measurement error. When measurement error is minimized, test reliability is high.

Other useful tests for children in the early years include the *Stanford-Binet Intelligence Scales for Early Childhood*. It was developed for children between the ages of 2 to 7 and assesses general intelligence. Subscales target fluid reasoning, knowledge, quantitative processing, visual-spatial processing, and working memory. The primary advantage of the Stanford-Binet is probably its connection to the version given to older individuals, for this implies that there is a great deal of research available on its rationale and validity. It is also relatively short, a useful characteristic for assessing young children.

The *Wechsler Nonverbal Scale of Ability* may be used with children who are 4 years of age or older. This test also measures general cognitive ability but it attempts to minimize the impact of verbal and linguistic abilities on the testing and the scoring. As a result, it may be the test of choice when working with children whose first language is not English. That being said, there is a long-standing debate about the existence of nonverbal intelligence. In a sense, the idea of a distinct nonverbal ability is contrary to the assumption of a general intelligence, or *g*, a concept that ostensibly covers

all intelligence. Additionally, it is quite difficult to administer a test without some communication between the examiner and the examinee. Thus verbal skills, though not targeted by the scales of a test, may still play a role in test performance. It does make sense that tests for very young children should not penalize them for immature language. The Wechsler Scale is not the only nonverbal test available for young children. Another nonverbal test is the *Primary Test of Nonverbal Intelligence*, which is available for administration to children between 3 and 9 years of age.

A very different measure is the *Multiple Intelligences Development Assessment Scales* (MIDAS), designed for children age 6 or older. This instrument differs from the Stanford-Binet and the Wechsler scale in that it assesses different types of “intelligences” as originally conceptualized by Howard Gardner. Subscales in the MIDAS cover the following domains: musical, kinesthetic, logical-mathematical, linguistic, interpersonal, and naturalist. One advantage of the MIDAS is, then, that it does not assume one general intellectual ability, or *g*, and might be able to identify special talents better than an IQ test. Still, the MIDAS was apparently constructed more as a measure of self-understanding rather than standardized measurement. This is consistent with Gardner’s own view of intellectual assessment.

Discussion

There are several options for intellectual assessment in early childhood. Some of the tests discussed in this entry focus on *g*, or general intelligence, the assumption being that there is one ability, and thus one test score, that includes all intellectual domains and performances. Alternatives include the KABC, with simultaneous and sequential processing scores, and the MIDAS, which focuses on domains of performance. The choice of a test depends in part on the purpose of the testing.

There are special considerations when assessing intellectual potentials in early childhood. Rapport tends to be more difficult and more important in the early ages, and children may suffer from stranger anxiety when positioned in a testing environment.

Intellectual assessments are typically judged in terms of their reliability, validity, and usefulness. In general, both reliability and validity are lower when testing very young children, in contrast to testing individuals later in childhood, adolescence, or beyond. Even tests with only marginal reliability and validity are used in early childhood; they are used for diagnostic purposes, not prediction. A test may be given to a young child to eliminate the possibility of a developmental disorder, for example. Also, it would be unrealistic to expect the same levels of reliability and validity when testing children in early childhood. After all, they are changing in many ways, at a rapid pace, so there is not as much stability in their behavior, and thus good reason to expect variations in test performances as well. That would translate to moderate or marginal reliability.

If a test is useful, it can compensate for its marginal reliability and/or validity. The tests discussed in this entry are useful in the sense that they allow an examiner to observe a child in a standardized fashion. This in turn allows for comparisons of young children with other children in an appropriate age range. It may even be that the test score is less important when testing young children than is the report that summarizes the child's performance on the examination. Reports that accompany test results allow an examiner to discuss rapport, attention, and other behaviors and situational factors observed during the testing. This information may be as useful, or even more useful, than a simple numeric test score, especially when working with young children.

INTELLECTUAL DISABILITIES

An *intellectual disability* is defined as significantly below-average general mental ability that occurs during the developmental period from conception through age 18 that coexists with problems in adaptation and significantly influences a child's experience and performance in preschool, kindergarten, elementary school, and beyond. Specifically, children with intellectual disabilities are determined at any point between conception through 21 to have low general intelligence that is significantly different from that of peers, and to demonstrate problems with adaptation to the environment, especially school and educational experiences. This entry provides information about the causes of intellectual disabilities, characteristics, diagnosis, issues related to early childhood education from birth through age 8, and education.

Causes

The cause of intellectual disabilities is often unknown. However, intellectual disabilities can result from genetic disorders, problems during prenatal development (pregnancy), complications during birth, and difficulties that occur after birth. Some of the more common genetic differences include Down syndrome, phenylketonuria (PKU), fragile X syndrome, Klinefelter syndrome, Turner syndrome, and Williams syndrome. Problems of prenatal development can involve infections and diseases in the mother, as well as environmental influences such as poisons ingested by the mother that include tobacco and alcohol. Fetal alcohol syndrome is a result of a problem during prenatal development. Difficulties during birth also can

occur. A prolonged and problematic labor in which the child is deprived of oxygen can cause brain damage that can result in intellectual disabilities. After birth, a child also can be exposed to toxins, such as lead from lead-based paint or tainted drinking water, or diseases that cause intellectual disabilities. Malnutrition also is a major cause of intellectual disabilities in many parts of the world.

Characteristics

Because one requirement of the definition of intellectual disabilities is below-average *general* intelligence, young children with intellectual disabilities may experience challenges in several areas of development. Children with intellectual disabilities from birth through age 8 may be delayed in achieving developmental milestones. Rolling over, sitting, crawling, and walking, as well as talking, problem solving, and developing social skills, are often experienced later by children with intellectual disabilities than their typically developing peers. Many develop self-care or adaptive skills such as feeding, dressing, and toileting at a delayed rate. Even so, children with intellectual disabilities are often not identified until they enter school and begin to have difficulties or fail in school.

Diagnosis

Intellectual disabilities are diagnosed in young children by considering two things. These are *intellectual functioning* and *adaptation to the environment*. Intellectual functioning refers to children's ability to learn, problem solve, and understand. When young children learn, problem solve, and understand at a rate that is much slower than typically developing peers, they may be diagnosed with intellectual disabilities. However, children also must have problems with adaptive behavior. Adaptive behavior involves daily living skills. These include learning to feed oneself, how to use the bathroom, and how to dress oneself. Getting along with others, such as

peers, family, and adults, requires adaptive behavior as well as communication skills.

Issues Related to Early Childhood Education

Physicians, psychologists, and educators are hesitant to provide young children a diagnosis of intellectual disabilities. The term or category of *developmental delay* is often used instead until the age of 9. The term *intellectual disabilities* replaced *mental retardation* with the enactment of Rosa's Law, which was signed by President Barack Obama in 2010. This occurred because mental retardation was considered a derogatory term and, therefore, Rosa's Law changed references to mental retardation to intellectual disability in federal law. In fact, the term for intellectual disabilities has a history of name changes due to perceived insults in previous terminology. Prior labels included *idiot* for profound, *imbecile* for moderate, and *moron* for mild intellectual disabilities. The term *mentally handicapped* also was used. Until the 1980s, educators used the terms *educable mentally retarded* (EMR), *trainable mentally retarded* (TMR), and in some cases *custodial mentally retarded* (CMR). Until recently, psychologists and pediatricians used terms such as *borderline*, *mild*, *moderate*, *severe*, and *profound* when describing the magnitude of intellectual disabilities.

Education

Young children with intellectual disabilities are served through the Individuals with Disabilities Education Improvement Act (IDEA) in the United States. The Division of Exceptional Children (DEC) of the Council for Exceptional Children (CEC) synthesized the research on evidence-based practices for young children with disabilities, which includes children with intellectual disabilities, and published it in *DEC Recommended Practices in Early Intervention/Early Childhood Special Education* (2014). Evidence-based practices for young children with disabilities include appropriate assessment, child-focused instructional

practices, family-based services, and teaming and collaboration. Further, young children with intellectual disabilities should be included in general early childhood programs whenever possible. Instruction and support should be implemented in the natural environments of children, which may be in the home or other community settings. Routine-based activities within the context of natural environments are recommended for children with intellectual and other disabilities. Some children with intellectual disabilities need the support of a speech-language pathologist and other related service professionals, which should be provided through collaboration with the family and other professionals in natural environments and inclusive settings. Finally, there have been numerous studies that report the benefits of early intervention and early childhood special education for children with special needs, including those with intellectual disabilities.

INTELLECTUAL DIVERSITY

In early childhood, intellectual diversity is one of many variables that affects human development, learning, and performance. Because the first years of life are shaped by many different biological, environmental, and social influences, young children grow and learn at very different rates. This results in a diversity of development unmatched during other periods of their lives. This entry summarizes the primary influences on differences, disabilities, and other variables that result in diversity in children's growth and development.

Changing Perspectives on Diversity and Differences

Professionals have long recognized that children display vast differences from the earliest ages, and various societies have responded quite differently to these children across the centuries. In his classic work on the history of people with intellectual disabilities, Richard Scheerenberger chronicled the different ways societies have treated children who displayed differences in their development. In the fourth century C.E., for example, St. Nicholas Thaumaturgus of what is now southern Turkey was regarded as the patron saint of children, including those with obvious intellectual disabilities. His care and advocacy for children with developmental differences contrasts with the practice of infanticide (killing of young children with disabilities or developmental delays) that was common during ancient Greek and Roman civilizations. From the Reformation (starting in the 1500s) until the late 18th century, treatment of children with developmental disabilities alternated between inhumane practices and great protections—by churches, professionals, and in common society. Between the late 1700s and the late 1800s, an era of humane treatment was slowly advanced by European medical professionals such as Philippe Pinel, Jean Marc Gaspard Itard, Edouard Seguin, and others who sought better ways to identify and treat children with obvious disabilities. This

approach continued as nations and cultures changed to meet advances in medicine, education, employment practices, and other aspects of society.

The 20th century saw increased attention to improving conditions for children in society. With this attention, many nations created protections and increased resources for their children and the professionals who serve them. This includes resources for children at an early age, and for children with diverse intellectual, language, economic, and other characteristics. Respect for young children and the diversity they represent is found in the 1959 *Declaration of the Rights of the Child*, a United Nations proclamation that increased worldwide attention to children's problems. This included malnutrition, which in turn increases future problems for children and their families, as well as the lack of access to education found on all the continents. The international attention continued when UNESCO identified the *International Year of the Child* in 1979, and again when the UN established the *Convention on the Rights of the Child* in 1989. To date, 194 nations have ratified this treaty that establishes legal norms for children.

Consistent with this attention, some nations have specifically identified young children with disabilities as the focus of legislation that provides federal and state resources to support their early growth and development. In the United States, for example, federal legislation passed in 1975 (P.L. 94-142: Education for All Handicapped Children Act) specifically identified the need to identify and serve children with intellectual and other differences as early as 3 years old; subsequent reauthorizations extended federal support for early intervention for infants and toddlers, and provided support for families and service providers (Pub. L. 108-446: Individuals with Disabilities Education Act).

The educational psychologist Maynard Reynolds observed that most societies across time gradually moved from subsistence economies with a "Darwinian social order" to societies with more efficient means of meeting their citizens' basic needs. With this change comes a shift from a society using its entire energy to feed and clothe its citizens (thus only the strongest members of

society survive) to a society where citizens can enjoy arts, leisure, and pursuits not involving daily subsistence. With this shift, Reynolds described an inevitable *progressive inclusion* of people once outside the center of society into the everyday mainstream. Societies who once ostracized, banned, or otherwise excluded people considered "outside" the social mainstream learned to accept those very individuals and groups as "insiders."

Reynolds observed that this movement toward progressive inclusion often applied to differences based on religion, race, ethnicity, and disability. This progressive inclusion thesis has driven the practice of identifying differences in young children, and providing services to them using universally effective practices. Whereas professionals previously identified disabilities and differences in children, then separated them to provide service based on these differences, many professionals now consider developmental differences as one of many characteristics that add to the diversity of human experience. With pedagogy principles such as universal design for learning, contemporary early educators seek interventions and services that are effective for children with a great deal of variability across a range of diversity characteristics. In this way recognition of differences in young children, including intellectual and other disabilities, is considered to be part of the overall diversity of early childhood.

Child-Centered Sources of Intellectual Diversity

There are many sources of intellectual diversity in young children that reside "within the child." Medical professionals have long sought to develop classification systems for children based on assumptions that intelligence was hereditary, best represented as a "general characteristic," and resisted change resulting from time and environmental exposure. Terminology for these classification systems was often crude. For example, William Ireland, a physician who spent many years refining his system, published a classification system titled *The Mental Affections of*

Children: Idiocy, Imbecility, and Insanity in 1898. Ireland and others continued to promote classification systems well into the 20th century based on medical diagnoses, IQ levels, and perceived limits in children's ability to learn. Relying on medical conditions and other etiologies for their schemes, many professionals provided little practical application guidance for educators and families.

By contrast, some professionals sought to understand young children's differences by studying their sequence of development, with less emphasis on intellectual deficits. Arnold Gesell exemplified this approach in his 1925 classic, *The Mental Growth of the Pre-school Child*. Gesell outlined a sequence of development through which children typically proceed, albeit at different rates. These developmental milestones incorporated expectations for motor, language, social, and other outcomes in children.

Gesell also published time frames at which most children reached developmental milestones. With a developmental sequence and an estimate of when such milestones might be met, Gesell and others advanced the idea that delays in acquiring these milestones might serve as an early warning system for professionals and families. Early identification of delays might yield actions that promote educational or other interventions that facilitate development in children. Today many high-quality developmental assessments are available to identify developmental progress in children. Some, such as the *Hawaii Early Learning Profile*, are normed with children representing deep diversity in language, family structure, ethnicity, and other child characteristics, including intellectual measures.

Regardless of the classification system used to describe childhood diversity, there are many child-centered variables that add to the diversity of children. Often these child-centered variables create challenges to children's growth and development. Biological factors that include genetic or chromosomal disorders such as Down syndrome, fragile X syndrome, or Tay-Sachs disease create conditions that require increased attention to children's health, language and intellectual development, physical stamina, and related conditions.

Although genetic testing and counseling have reduced the incidence of these conditions, many young children with these conditions still enter the system of early childhood care and education. Similarly, other child-centered conditions resulting in intellectual and other developmental challenges result from trauma during birth, poor maternal health during pregnancy, or substance or alcohol abuse during pregnancy. Although these prenatal risk factors might result in noticeable intellectual and other disabilities, they might have no discernable effect at all. Any of these child-centered sources can present challenges to professionals unprepared for (or knowledgeable about) the conditions and the diversity in children's learning and development that result.

Environmental Sources of Intellectual Diversity

There is an array of exogenous or environmental variables that contribute to the diversity of growth and development of young children. One variable involves children's nutrition during their early years. In many parts of the world a reliable food supply keeps children adequately fed and hydrated, promoting healthy brain growth and proper development of other organs, bones, and muscles. In other areas, however, children experience malnutrition from an inadequate food supply, as well as myriad problems resulting from dehydration and unsanitary drinking water. These conditions are known to have a negative impact on brain development, and the resulting cognitive functions last long into adulthood.

For many children, poverty has a similar insidious effect on intellectual and physical development. The relationship between poverty and cognitive function is one of a multiplier effect. Deep poverty affects families' access to health care, nutrition, and sanitation that, in turn, serve as risk factors for human development. When these risk factors assault children's growth during their most vulnerable developmental years (i.e., the first 5 years of life), the cumulative impact may contribute to lowered intellectual development affecting

language, problem solving, memory, and creative expression. In addition, children living in poverty often begin school already behind children whose families are not affected by economic distress. The popularized slogan *war on poverty* has been used to generate support for children's issues by minimizing the impact of these conditions on children's growth and development.

A third source of environmental variables that affect intellectual and other development involves the impact of illness and injury. Many childhood illnesses affect children's development. Infectious agents such as chicken pox, measles, pneumonia, as well as viral and bacterial infections that cause meningitis, can result in seizures, inflammation of brain tissue, neurological problems, speech impairment, and hearing loss, all with a potential impact on intellectual development. Poisoning, most commonly from lead or mercury, is known to lead to diminished intellectual and physical development. Also, injuries continue to be a major cause of disability in childhood. Injuries may be the result of falls, automobile accidents, water events, and other unintentional actions; sadly, some injuries are the result of abuse and neglect. In addition to the obvious psychological impact of these events on children, they also take a serious toll on children's intellectual development.

Finally, a major source of variance in the intellectual development of children stems from the language environment in which children live. In a monumental work on the role of language environments, Betty Hart and Todd Risley examined the impact that "language rich and language poor" home environments have on children's language. Often correlated with poverty or lower socioeconomic status (SES), Hart and Risley chronicled the impact of daily exposure to the language diversity of adults and other children, showing that children's vocabulary growth was strongly influenced by *how much* parents talked to them. Language-rich environments had a stark impact on children, and at a far earlier age than previously believed. In a single year, children in language-rich environments heard up to 11 million words, while children in language-poor environments heard an

average of 3 million words. By age 3, children from language-rich, higher-SES environments averaged 3 times more vocabulary in their daily communications than children from language-poor environments. This disparity increased as children grew older, although highly structured, language-rich educational programs dampened the discrepancy somewhat. Given the critical role that language has on intellectual development, the need for robust language environments has become a cornerstone of most early childhood programs.

Increasing Early Childhood Educators Responsiveness to Intellectual Diversity

As societies increase the value that they place on healthy children, they increasingly expect that children will have access to high-quality early education experiences. Contemporary early childhood programs respond to a population of children made diverse by a host of cultural, ethnic, language, religious, and intellectual differences. Professional organizations such as the National Association for the Education of Young Children and the Council for Exceptional Children's Division for Early Childhood advocate for active and effective practices for a diverse population of young children. Their recommendations include the following:

- Early childhood professionals should increase their knowledge of diverse populations of children, including those with intellectual, cultural, language, and other forms of diversity.
- Early childhood professionals recognize that intellectual, cultural, language, and other forms of diversity are the expected norm in contemporary early childhood.
- Educators who prepare early childhood professionals should increase opportunities for future professionals to gain meaningful practical applications with diverse populations of children during their preparation.
- Early childhood professionals should increase support for educators who teach diverse populations of children.

As the expectation for intellectual diversity in children matches the expectation for cultural, language, and other forms of diversity, the creativity, excitement, and effectiveness of early childhood educators and programs continue to grow.

INTENTIONAL TEACHING

Intentional teaching is the “planful, thoughtful, and purposeful acts teachers implement to ensure that young children acquire the knowledge and skills (content) they need to succeed in school and in life. Intentional teachers use their knowledge, judgment, and expertise to act with specific outcomes or goals in mind for children’s development and learning, and they integrate and promote meaningful learning in *all* domains” (Epstein, 2014, p. 242). Although intentionality had previously appeared as a term in early childhood pedagogy (for example, in the writings of David Berliner and Robert Pianta), the concept gained prominence with the 2007 release of *The Intentional Teacher* by Ann S. Epstein, published by the National Association for the Education of Young Children (NAEYC) (and revised in 2014). The book reflected the field’s growing recognition that teachers had to play a more visible role in early learning and that the educational curriculum must explicitly address content. This entry explains the concept of intentional teaching, discusses general best practices in intentional teaching, and details the topics and specific teaching strategies used in intentional teaching.

Intentional teaching reframes the sometimes strident debate between the ideas of child-initiated education and adult-directed education. It refutes both the claim that children do not learn academics when all they do is “play” and the claim that early social-emotional development is short-changed by explicit instruction. As the Committee on Early Childhood Pedagogy concluded in its report *Eager to Learn*:

Children need opportunities to initiate activities and follow their interests, but teachers are not passive during these [child]-initiated and directed

activities. Similarly, children should be actively engaged and responsive during teacher-initiated and -directed activities. Good teachers help support the child's learning in both types of activities. (National Research Council, 2000, 8–9)

Instead of a dichotomy, intentional teaching posits that children learn through a balance of *child-guided* and *adult-guided* experiences. In child-guided learning, children acquire knowledge and skills mainly through their own exploration, including peer interactions. In adult-guided learning, teachers plan or take advantage of opportunities to introduce information and model skills. In neither instance is either person passive, but one or the other takes the lead. Choosing the most appropriate method(s) depends on the particular content and/or child's developmental and ability level. Intentional teachers draw on a repertoire of proven instructional strategies to carry out the option(s) that fit the situation. Their choices are grounded in research on child development and effective teaching practices, and they observe children and modify their strategies as needed.

The division between child-guided and adult-guided learning is not rigid and for any content area, it evolves over time. Take language and literacy as an example. Young children begin to build their speaking and listening skills through spontaneous and natural conversations (child-guided experience). However, they also learn syntax and vocabulary from adults, and teachers often make a point of introducing new words and more complex sentence structures (adult-guided experience). Likewise, while children are born with the capacity to hear and reproduce the sounds of speech, and are inherently motivated to communicate (child-guided), identifying the letters of the alphabet is not something that children can do intuitively. Letter forms and their names are culturally determined and are thus learned from knowledgeable grown-ups (adult-guided). Intentional teaching defines what types of learning are best scaffolded—supported and gently extended—by each type of experience and lays out the strategies for doing so.

Intentional teaching begins with these general best practices: *structuring the physical learning environment* by using space and materials to accommodate children's diverse interests, families and cultures, languages, developmental levels, and special needs; *scheduling the program day* to offer a rich and varied mix of learning opportunities in a supportive framework of routine; *interacting with children* in a warm and authentic manner to encourage initiative and social relationships; *building relationships with families* to establish mutual respect, share information, and extend school learning into the home; and *assessing children's development* with validated methods to plan for the child- and adult-guided strategies that will further support growth.

Topics and Teaching Strategies in Intentional Teaching

With these basics in place, intentional teaching then draws on current child development and educational research to identify child- and adult-guided topics and teaching strategies in each of eight content areas: approaches to learning, social and emotional learning, physical development and health, language and literacy, mathematics, science, social studies, and the creative arts.

In the area of *approaches to learning*, intentional teaching is organized as follows:

1. Openness to experiences (exploring materials, ideas, people, and events)
 - Child-guided experiences foster taking the initiative and engaging with materials.
 - Adult-guided experiences foster planning and engaging with ideas.
2. Processing experiences (dealing with the physical and interpersonal environment during and after a learning experience)
 - Child-guided experiences foster solving problems and using resources.
 - Adult-guided experiences foster reflecting and following up.

In the area of *social and emotional learning*, intentional teaching is organized as follows:

1. Emotional learning (understanding, labeling, expressing, and regulating feelings)
 - Child-guided experiences foster developing a positive self-identity and feeling empathy.
 - Adult-guided experiences foster developing feelings of competence and recognizing and labeling emotions.
2. Social learning (relating to others and understanding social conventions)
 - Child-guided experiences foster developing a sense of community; building relationships; and engaging in cooperative play.
 - Adult-guided experiences foster engaging in conflict resolution and developing a framework for moral behavior.

In the area of *physical development and health*, intentional teaching is organized as follows:

1. Movement skills (developing physical or motor abilities)
 - Child-guided experiences foster *locomotor skills*: crawling, walking, running, climbing; *stability skills*: turning, twisting, bending, straightening, curling, stretching/extending, swinging, swaying, pushing, pulling, rising, falling, dodging, stopping; *manipulative skills*: throwing, kicking; and *fine-motor skills and eye-hand coordination*: grasping, pinching, tearing.
 - Adult-guided experiences foster *locomotor skills*: hopping, galloping, sliding, slithering, marching, plodding, leaping, chasing, fleeing, skipping; *stability skills*: transferring weight, balancing, jumping/landing, rolling; *manipulative skills*: catching/collecting, dribbling, volleying, punting, striking with a racket, striking with a long-handled instrument; and *fine-motor skills and eye-hand coordination*: cutting, folding, writing.

2. Movement concepts (understanding where, how, and in relation to what the body moves)
 - Child-guided experiences foster *space awareness*: self space, shared space; *effort awareness*: time (speeds); and *body awareness*: with self (body parts, body shapes).
 - Adult-guided experiences foster *space awareness*: levels, directions, pathways; *effort awareness*: time (rhythms), force, control/flow; and *body awareness*: with self (roles) with other movers and objects.
3. Personal care and healthy behavior (taking care of one's bodily needs and health)
 - Child-guided experiences foster feeding and dressing oneself (using serving and eating utensils; putting on and taking off outerwear, shoes, dress-up clothes) and exercising.
 - Adult-guided experiences foster washing hands and brushing teeth; practicing personal hygiene; differentiating between healthy and unhealthy foods; and following safety procedures.

In the area of *language and literacy*, intentional teaching is organized as follows:

1. Language (developing competency in speaking, listening, and comprehending)
 - Child-guided experiences foster sound awareness and production; conversational skills; and dual language learning.
 - Adult-guided experiences foster phonological awareness; vocabulary; and knowledge of narrative/comprehension.
2. Reading (understanding how print works and the relationship between spoken and written language)
 - Child-guided experiences foster visual discrimination skills; environmental print knowledge; print awareness; and motivation to interact with printed materials.
 - Adult-guided experiences foster understanding the relationship between

spoken and written language as well as alphabet knowledge: letter identification and letter-sound knowledge.

3. Writing (creating and using print to convey or represent one's ideas)
 - Child-guided experiences foster fine-motor skills and awareness of the purposes and functions of writing.
 - Adult-guided experiences foster letter and word writing and awareness of the conventions of spelling, grammar, syntax, and punctuation.

In the area of *mathematics*, intentional teaching is organized as follows:

1. Number and operations (understanding what numbers are and how they work)
 - Child-guided experiences foster intuiting number and its properties and performing informal arithmetic.
 - Adult-guided experiences foster counting and numeration and performing simple arithmetic.
2. Geometry and spatial sense (understanding shapes and relationships between objects)
 - Child-guided experiences foster familiarity with two- and three-dimensional shapes and orienting self and objects in space.
 - Adult-guided experiences foster creating, naming, and transforming shapes and articulating position, location, direction, and distance.
3. Measurement (determining quantity and learning proper measuring techniques)
 - Child-guided experiences foster comparing (seriating) or estimating without counting or measuring.
 - Adult-guided experiences foster counting or measuring to quantify differences.
4. Patterns, functions, and algebra (identifying patterns and describing change)
 - Child-guided experiences foster recognizing, copying, and creating simple patterns and recognizing naturally occurring change.

- Adult-guided experiences foster identifying and extending complex patterns and controlling change.

5. *Data analysis* (collecting, categorizing, representing, interpreting, and applying information)
 - Child-guided experiences foster making collections and sorting (classifying) by quantitative attributes.
 - Adult-guided experiences foster representing gathered information and interpreting and applying information.

In the area of *science*, intentional teaching is organized as follows:

1. Scientific procedure (using the scientific method to learn about the world)
 - Child-guided experiences foster observing and classifying.
 - Adult-guided experiences foster experimenting; predicting; and drawing conclusions.
2. *Learning and sharing scientific ideas* (developing and communicating one's scientific understanding)
 - Child-guided experiences foster learning about tools and technology as well as communicating ideas.
 - Adult-guided experiences foster learning about the natural world and learning about the physical world.

In the area of *social studies*, intentional teaching is organized as follows:

1. Social systems (learning the norms, values, and procedures that affect human relationships)
 - Child-guided experiences foster valuing diversity and learning about community roles.
 - Adult-guided experiences foster creating and following rules and creating and participating in a democracy.

2. Social concepts (becoming familiar with basic ideas in economics, history, geography, and ecology)

- Child-guided experiences foster understanding simple economics and understanding history.
- Adult-guided experiences foster understanding geography and appreciating ecology.

In the area of *creative arts*, intentional teaching is organized as follows:

1. Visual art (creating with two- and three-dimensional materials)

- Child-guided experiences foster manipulating two- and three-dimensional art materials; making representations from experience; making accidental representations; and making simple representations.
- Adult-guided experiences foster naming art materials, tools, and actions; becoming adept at using two- and three-dimensional art materials and tools; making representations using imagination; making intentional representations; and making complex representations.

2. Music (creating with sound)

- Child-guided experiences foster exploring sounds; exploring the voice; and playing simple musical instruments.
- Adult-guided experiences foster singing and understanding rhythmic and tonal qualities.

3. Movement (creating by moving the body)

- Child-guided experiences foster moving the body in different ways and imitating simple movements.
- Adult-guided experiences foster imitating complex movements and creating movement sequences.

4. *Dramatic (pretend) play* (creating play scenarios by imitation and invention)

- Child-guided experiences foster imitating gestures, sounds, and words; using simple props; and pretending alone or with one other person.
- Adult-guided experiences foster imagining characters and events; creating complex props; and pretending with two or more people.

5. Art appreciation (understanding artistic expression and making aesthetic choices)

- Child-guided experiences foster focusing on one aspect of a work of art; making simple aesthetic choices; and recognizing and understanding the feelings expressed through art.
- Adult-guided experiences foster naming artistic media, elements, and techniques; focusing on multiple aspects of a work of art; articulating the reasons for aesthetic choices; describing the feelings expressed through art; and recognizing cultural and temporal influences on art.

Intentional teaching is increasingly recognized as an essential component of program quality. It is a policy position of the National Association of Early Childhood Specialists in State Departments of Education that teachers receive training in providing intentional and appropriate instruction.

INTERDISCIPLINARY MODELS

Interdisciplinary models of contemporary early childhood education refer to models that have their roots in developmental psychology, educational psychology, and related fields and have implications for practice today. This entry focuses on three types of models that have received recent attention and had a significant influence on early education, especially for children from the age of 3 through the first years of formal schooling. These models emphasize the need for intentional teacher–child interactions, family involvement and support, and community resources to foster children’s learning and development.

Background

Early childhood education, especially high-quality PreK–3 education, is now widely recognized as one of the best ways to improve the academic achievement and well-being of children from varied backgrounds. This recognition is partly due to the enormous amount of research conducted in the past two decades establishing the positive effects of high-quality programs for children and their families, at least in the short term. These efforts have, in turn, led to the creation of models to examine the links among

features of programs and positive child outcomes that have lasting effects.

The models briefly described in this entry were selected because they integrate multiple theoretical perspectives and extensive research, as well as attempt to inspire and explain effective programs and practices. These models have some basis in the following theories:

- Urie Bronfenbrenner’s bioecological theory
- Jean Piaget’s constructivist theory of cognitive development
- Lev Vygotsky’s sociocultural theory
- John Bowlby’s and Mary Ainsworth’s attachment theory
- Social learning theories, such as Albert Bandura’s
- Self-determination and other theories of motivation

In addition, the three models incorporate recent research on how children develop competencies within general domains (e.g., physical, cognitive, social) and knowledge domains (e.g., literacy, mathematics), as well as on key processes that underlie or contribute to these competencies (e.g., self-regulation, relationships) in early educational settings.

Models and Programs

Transactional Models

Transactional developmental models focus on actual interactions or exchanges between teachers and children (or between child peers or children and materials) that are sustained over time in classrooms and directly affect children’s learning and development. According to bioecological theorists, these exchanges are “proximal processes” (within microsystems) that are reciprocal and bi-directional in nature, and are affected by structural features of program quality, such as teacher education, teacher–child ratios, and classroom materials, as well as distal processes and systems, such as state regulations and financial support of early childhood programs.

Transactional models are unique in the extent to which they focus on everyday interactions in

classrooms (especially teacher–child exchanges), consider children’s and teachers’ attributes and contributions to these exchanges, and examine specific skills developed through these exchanges over time. Clair Cameron has described a transactional model that looks at exchanges between children and teachers with attributes shown in previous research to be critical for adaptive functioning. For example, child attributes include their biologically based temperaments that affect abilities to control emotions and behavioral impulses; their foundational cognitive processes (e.g., executive function), motor skills (e.g., body movement, word articulation), and approaches (e.g., curiosity, persistence) that affect later learning; their emergent academic skills (e.g., literacy, math concepts); and their physical health. Teacher attributes include their self-efficacy or perceived abilities to enhance children’s learning in different domains and their classroom management and organizational skills.

Importantly, these personal attributes influence the number of transactions that occur between teachers and children in major domains of learning (e.g., language and literacy, social and emotional skills), and the extent to which the transactions are appropriate for the child’s skill level. The model posits that both the quantity and quality of these transactions determine the potential for children to develop competencies in a particular domain. For example, a child with aggressive tendencies may experience limited opportunities for positive exchanges with teachers to support his or her literacy development, especially with teachers with low self-efficacy.

One well-known intervention program that focuses on teacher–child transactions is *Tools of the Mind*, developed and studied extensively by Elena Bodrova and Deborah Leong and others. Preschool teachers are trained to provide learning activities that promote children’s self-regulation or executive function and related skills, by ensuring that they interact with children individually and attend to their interests and skills. For example, one activity requires teachers to help children create plans for their play, put these plans in drawing

or written form, and follow the plans throughout the day. Studies suggest that the *Tools* program enhances children’s executive function, language and literacy skills, and social skills.

Another example of a transactional model is the *Teaching Through Interaction (TTI)* framework developed by Bridget Hamre, Robert Pianta, and others. The TTI model also focuses on proximal processes (within a bioecological system), and is grounded in multiple theoretical perspectives and empirical research. The everyday interactions, especially between teachers and children, are classified into three general domains: emotional support, classroom organization, and instructional support. The emotional support domain focuses on interactions that produce a positive classroom climate, enhance teacher sensitivity to children’s needs for positive relationships and autonomy, and demonstrate respect for children’s interests and perspectives. The classroom organization domain focuses on enhancing self-regulatory and other skills that underlie many social and academic skills important for school adjustment and success. Effective interactions in this domain include proactive management strategies, efficient use of instructional time (maximizing opportunities to learn), and provision of engaging activities and materials. The instructional support domain encompasses activities that enhance higher-order thinking skills, incorporate clear and positive feedback, and facilitate sophisticated language use. Multiple studies have confirmed the value of these kinds of activities for fostering children’s learning and development in early educational programs.

The TTI framework has led to the development of a teacher professional development system—*MyTeachingPartner (MTP)*—that emphasizes intentionality and reflection on interactions in the three domains. Elements of the system include having teachers view video clips of high-quality teacher–child interactions, record their own classroom practices and discuss these with coaches, and make plans for improving interactions with children. Initial studies indicated that preschool teachers who participated in more elements of the system (including consultation) improved the quality of

their interactions with children in several domains, and children in their classrooms also made gains in academic and social skills.

Collaborative Parent–Professional Partnership Models

Collaborative partnership models in early education, focusing on relationships between parents and early childhood educators and other professionals, also stem from a bioecological framework and other developmental theories. They examine professional–parent–child interactions within settings (microsystems) and connections between settings (mesosystems), such as home and school, and their influences on children’s learning and development. Susan Sheridan, Lisa Knoche, Christine Marvin, and their colleagues propose four key components of collaborative partnership models: (1) a focus on enhancing parent–child interactions, (2) the use of “natural teaching” in everyday activities, (3) the use of a data-based, problem-solving approach, and (4) the use of evidence-based practices.

The first key component involves having early educators or interventionists observe, support, and enhance parent–child interactions as they occur. This can be done through noting parents’ strengths, attending to children’s responsive behaviors and developing competencies, providing developmental information, and modeling positive strategies to support and engage children in learning. The second component of the model involves teaching parents to identify and nurture natural learning opportunities within everyday activities in different settings (e.g., home, park, shopping) to foster children’s developing language, social, and other skills. The third component involves a structured, problem-solving approach to promote positive child outcomes as well as parent skills. This approach includes identifying shared goals for children, collecting and analyzing pertinent data (e.g., observations, reports), developing strategies to promote goals and address concerns, and evaluating the effectiveness of the strategies. The process can be provided by an early educator working collaboratively with family members, and might

also be facilitated by a professional consultant (e.g., mental health provider, special educator). The final component stipulates that the strategies included in intervention plans be based on evidence-based practices, such as research on effective ways to help children regulate their behavior and emotions.

A number of effective intervention approaches can be described according to some or all of these components, such as The Incredible Years parent training program developed by Carolyn Webster-Stratton and her colleagues. The Getting Ready intervention is introduced here because it incorporates components of a collaborative parent–professional partnership model, and emphasizes promoting the relationship between parents and early education professionals. The Getting Ready intervention is integrated within early education programs such as Head Start and takes place during regular home visits or group meetings. This intervention was designed by Susan Sheridan and others to enhance children’s readiness for formal schooling and incorporates the following general strategies:

- Establish and maintain parent–professional relationships, through listening and responding to parent priorities and concerns
- Share observations/knowledge of child’s progress
- Identify shared developmental expectations for child
- Brainstorm ideas for helping child meet expectations
- Observe parent–child interactions and provide feedback
- Monitor the child’s development and discuss needed adjustments in interactions and/or learning opportunities

Studies suggest that the Getting Ready intervention can be implemented with fidelity by early childhood professionals and has a positive influence on parenting behavior as well as pre-school children’s socioemotional and language and literacy skills.

Another example of a well-regarded collaborative parent–professional model is the Yale Child

Study Center School Development Program (SDP) developed by James Comer. Although this model was originally intended to reform elementary schools, it was later applied to the education of younger children in the Comer/Zigler Initiative (CoZi), which combined the SDP with Edward F. Zigler's School of the 21st Century (21C). At the heart of the SDP is the notion that schools must attend to all aspects of children's development (e.g., physical, cognitive, psychological, ethical) to foster optimal learning. In addition, meaningful learning occurs through positive relationships with adults in the school and community.

The SDP provides an operating system to ensure adults work together to support children's learning and development. This system involves three teams—a parent team, a school management team, and a student and staff support team—who work separately and collaboratively on a comprehensive school plan to set and monitor selected social and academic climate goals. The school plan inspires assessment and modification of practices as well as staff development goals. The success of the SDP, implemented in more than 1,000 U.S. schools, is attributed in large part to the guidelines established for enhancing relationships and interactions between team members. These guidelines include no-fault problem solving, consensus decision making, and collaborative efforts focused on fostering the development of children. Many studies have demonstrated the effectiveness of the SDP for enhancing the social climate of schools as well as student academic achievement.

Community School Models

Community school models encourage public schools to promote school readiness and academic success by supporting families and children from birth, especially those living in poverty. Such models can include services such as high-quality child care, parent education, and referrals to other community services (e.g., health care, developmental screening). This is a comprehensive model in its inclusion of multiple ecosystem influences and connections, stimulated by research demonstrating

the serious need for access to high-quality programs and services in the United States to help support families during the critical early childhood years. This model is also supported by recent research showing the importance of easing transitions between home and school, and preschool and kindergarten, for children's adjustment in school and later learning.

The School of the 21st Century (21C) model emphasizes promotion of children's development across domains through fostering positive relationships with parents, and providing (noncompulsory) access to a range of family support services. 21C incorporates six program components: (1) family outreach (e.g., home visits, playgroups, workshops), (2) high-quality child care for children ages 3 to 5, (3) before- and after-school programs for school-age children, (4) community-based health care services (e.g., nutrition and fitness, physical and mental health), (5) training and support for local child care providers, and (6) other information and referral services. 21C has been incorporated in over 1,300 schools, and a national evaluation study indicated that the preschool and child care programs were of higher quality and the attending children had higher achievement scores through second grade than those in other large-scale studies.

These interdisciplinary models include elements of early educational programs that are important, if not essential, for improving practice and fostering children's learning and development.

INTERNSHIPS

The term *internship* refers to a learning experience provided for selected and prepared individuals who desire to become professional practitioners. In teacher training in the United States, internship, which is also often called student teaching, refers to an extended field placement during initial teacher training in which prospective teachers (also called student teachers), assume teaching responsibilities in the classrooms of cooperating teachers. Internship in the field of education is usually preceded by observational participation and student teaching or equivalent clinical experiences in a school environment. It is planned and coordinated by the teacher education institution in cooperation with one or more school systems.

Overview

The internship is a widely accepted practice in teacher education and a critical experience toward preparing new teachers to be effective and successful in the classroom. The internship is in the final phase of a teacher education program designed to instill professional behavior. It is a time to focus on teaching and working with young children and their families under the guidance and support of cooperating teachers and university supervisors. The goal of the internship is to provide experiences in the classrooms with clinical teachers providing close supervision and mentoring and to facilitate the learning process for preservice teachers who lack classroom teaching experience.

In general, an internship includes classroom-based teaching and assessment experiences, observation, home visits, participation in eligibility meetings and individualized education programs, collaborative relationship building with professionals and families, and working-hour daily activities of the cooperating teacher. During an internship, student teachers are provided opportunities to work in applied early childhood settings under the supervision of cooperating teachers. The internship helps student teachers (a) gain and enhance their perceptions of teaching practices and the elements of teacher sensitivity and effectiveness, (b) develop pedagogical and content-specific knowledge, and (c) develop personal practical knowledge about the work of teaching. Furthermore, with the knowledge of teaching emerging directly from the activity of teaching, an internship provides prospective teachers with an opportunity to construct their own understandings of teaching based on the practical dilemmas they encounter in the field.

Cooperating Teacher

Cooperating teachers, who support and mentor interns, play a key role during the internship. Because an internship provides an apprentice-type introduction to teaching, cooperating teachers provide models of teaching behaviors and serve as gatekeepers to the experiential learning of preservice teachers. The intern's steady initiation into the classroom is carefully managed and monitored. Cooperating teachers serve as models who guide prospective teachers in applying theory and instructional approaches to real settings. It is believed that cooperating teachers significantly influence student teachers' beliefs about the teaching profession, professional norms, and teachers' decisions on content areas.

Cooperating teachers have an important responsibility to be a mentor and instructor in issues specific to their workplace and the needs of the children and families that are served. They are required to observe interns, provide feedback, make professional conversation, and collaborate successfully. With the assistance of the university supervisor, the cooperating teacher acts as a mentor

by providing support and guidance for the intern. The responsibilities of the cooperating teacher include encouraging interns to find their own teaching style, overseeing interns' planning, monitoring the interns learning about children and their families, and offering feedback.

Supervision

Supervision is a very important aspect of the development and induction of student teachers into the profession. Supervisors who are knowledgeable about the field help student teachers have support systems that encourage effective practice. The primary purpose of supervision is the improvement of teaching and learning through the acquisition of a deeper understanding of the learning-teaching process. Supervision focuses on the development of a professionally responsible teacher who questions his or her own performances, being receptive of others' advice and input.

The university supervisor serves as a link between the university and local child care centers, providing support and guidance to both the student interns and the cooperating teacher. The roles of the supervisor are to encourage interns to have smooth communication with the cooperating teacher and to observe and evaluate interns' performance in a classroom setting. The responsibilities of the university supervisor for the internship are to meet with the intern and cooperating teacher to establish internship expectations, determine a schedule, and encourage open communication and a collaborative approach to supporting and providing feedback to the intern.

The relationship between the supervisor and student intern is critical during the whole internship. It requires a close collaboration between the cooperating teacher and supervisor as colleagues, respecting each other's contribution. In spite of the great importance of supervision in an internship, supervisors face several challenges and difficulties, including difficulty in balancing support and assessment of student teachers, unclear role and program expectations stemming from a lack of preparation and support for university supervisors, and cultural norms of schools and classrooms.

Challenges

The National Council on Teacher Quality has revealed several challenges that student teaching in the United States faces. First, teacher preparation programs often have more students than can be provided a quality student teaching experience in local school districts. Second, a substantial number of interns are improperly supervised by their own institution. Third, institutions do not provide sufficiently clear and systematic descriptions about the qualification of cooperating teachers. Fourth, due to the dependence of institutions on school districts to provide intern placements, institutions convey inability, especially in the selection of the cooperating teachers. Last, not many institutions provide interns with adequate guidance and feedback on their abilities as a teacher.

INTERPRETING ASSESSMENT DATA

Interpreting assessment data is a process of understanding the purpose, design, and scores of assessments. Proper interpretation provides information

on how children are doing in comparison to other children their age, how they are progressing over time, and how information relates to the goals of a teacher, curriculum, or early childhood program. Data literacy skills and connection of the measures to the intentions of teaching will aid interpretation. This entry focuses primarily on the interpretation of norm-referenced assessments, because these assessments often come with a variety of scores and numbers that require specialized knowledge to interpret and understand. Direct assessments that do not follow standard procedures are also discussed. In addition to direct assessments of children, this entry briefly explores the interpretation of classroom quality assessments.

Overview

Early childhood professionals' interpretation of assessment data serves as the basis of evidence-based decision making to support children's learning and development. For professionals who are asked to interpret assessment data created by professional test developers, the results and implications of such results can be daunting. Interpreting assessment data improves with practice, like any skill, and can be a part of every early childhood professional's toolkit. Interpretation can be thought of as gaining insight into children's skills and abilities, and the environments which they experience.

Statistics Used in Assessment Reporting

Basic data literacy requires certain vocabulary. Terms used with child assessment results are defined below:

Sample: Large groups of children with whom the assessment has been conducted. These groups of children become the representatives of the population to which the norm-referenced assessments can be generalized. Scores from these children are used to create comparison data and allow any one child's scores on the assessment to be compared to this group. To allow children across the nation to be compared, the sample will need to include

groups of children from across the nation, representing multiple race, ethnic, and socioeconomic subgroups. This group is also referred to as the norm group or normative sample, because it is the group representing a normal distribution of scores.

Mean: The arithmetic average of a group of scores, calculated by summing all of the scores and dividing by the number of scores.

Percentile Rank: A ranking based on the norm group that represents the percentage of the sample that scored at or below the same score.

Standard Score: A ranking based on the norm group that represents how children are doing in comparison to their similar-age peers, with a certain number set as a mean, and significant differences from the mean being interpreted in terms of the standard deviation. (A confusing overlap exists in the use of the word *standardized*. A standardized assessment is conducted with all children in the same way. A standard score is norm-referenced.)

Standard Deviation: This number represents the spread of the scores within the sample distribution. The formula is primarily based on how all of the scores differ, or deviate, from the mean.

Standard Error of Measurement (SEM): This number measures how much error is part of a test. It has a reciprocal relationship with reliability, in that the more reliable a measure is, the less error it has. SEM can be used to construct confidence intervals around a score, in this way: Score (+/-) SEM.

Confidence Interval: A range within which one can be confident that the child's score would fall if the child were to, theoretically, be assessed multiple times.

Questions of Interpretation

Questions framing the interpretation of assessment data for young children include the following: (1) Are they on target for their age? (2) Are they progressing appropriately? (3) Are they meeting specific benchmarks of learning and development?

Assessing whether children are on target for their age will typically be conducted through a structured assessment or observation. However, the structure of assessment can be discreet, with the child not knowing that he or she is being assessed, such as with a portfolio of the child's work or a structured observation of play. With these kinds of assessments, the recommendations of WestEd's PITC (Program for Infant Toddler Care) curriculum are helpful. The program recommends three steps: watch, ask, and adapt—meaning that adults should watch the child's responses, ask themselves what they mean, and adapt to them. This is an ongoing process of intentionally attempting to understand various aspects of development, the child's environment, and the connections between environment, behavior, and development and learning.

While ongoing observation and consideration of children's work are important ways to understand children without disrupting their play, they are open to interpretation by professionals who may have large variations in their training and understanding of child development. Even highly trained professionals can fail to notice that a child may need intervention due to a well-intentioned focus on the child's strengths. Therefore, direct assessments of children provide structure to the question of how a child is doing compared to other children his or her age. These also vary in form and interpretation from a checklist of tasks to more rigorously developed standardized assessments.

For checklists, the final score may be a sum of the number of tasks the child could perform. This sum is compared to a range of scores that can be interpreted in two ways—(1) the child did perform as well as peers of similar age or (2) the child did not perform as well as peers of similar age. While this type of assessment is valued for the ease of administration, with some items possible to observe in the child's natural play, a limitation is the specificity of interpretation. That is, one can only gather from this assessment that a child is or is not developing typically, according to what was observed that day. However, one cannot gather from this type of assessment if there is a large or small difference

in a child's performance compared to other children his or her age.

A norm-referenced, standardized assessment can give this kind of information with more detail. Understanding some basics about how norm-referenced assessments are developed and how they are reported is essential to interpreting this data. Norm-referenced assessments are primarily used to compare children to other children like them. Thus, the term *norm-referenced* tells one that the assessment will refer to a normative group of children who are approximately the same age or grade.

The standard score is named thus because the range of each norm groups' raw scores are standardized so that the *mean*, or arithmetic average, score for each norm group is assigned the same score. Scores more than 1 and less than 2 standard deviations from the mean should be given more attention, as they are slightly outside the area of typical development. Scores more than 2 standard deviations from the mean should alert the educator that the child's score is typical for only 2.5% of the highest or 2.5% of the lowest scores in the norm group. These rare scores may indicate that the child has a particular strength in this area or is possibly in need of professional assistance.

A second question early childhood professionals will ask when interpreting data is "Are the children in my care progressing appropriately?" Teachers want to know how children are doing over time. This can be accomplished through ongoing observations such as those developed by HighScope COR and Teaching Strategies GOLD. Ongoing authentic assessment, conducted while the child is at play in his or her typical environment, captures anecdotal data that can be analyzed and compared over time. Collection and interpretation of these data requires training by the developers of the observational tools.

In addition to norm-referenced scores that compare a child to other children of the same age, some standardized assessments provide a *growth scale value*. A growth scale value is a score that can be compared from one assessment to another to understand children's increase or decrease of knowledge, skills, or abilities. Growth scale values

can be interpreted as a change in children's performance, with guidance on significant change often provided by the technical manual of the assessment.

A balance between standardized assessments and more authentic assessments are measures created for progress monitoring, such as the Individual Growth and Development Indicators (IGDIs) for Infants and Toddlers. The use of progress monitoring is particularly important for early interventionists who can plan and implement ways to assist children with, or at risk of, developmental delays. However, progress monitoring can also be used with typically developing children. Dale Walker, Judith J. Carta, Charles R. Greenwood, and Joseph F. Buzhardt describe the use of these measures to assist in interpreting and using data on children's development over time.

Interpreting child assessment data of ongoing observation and standardized assessments gives insights into how children are doing compared to others their age and how children are progressing. The actions taken in response to these interpretations are outside the scope of this entry. However, some assessments give more insight into what to do next, as they are designed around particular standards and objectives. These assessments, known as *criterion-referenced assessments*, are interpreted simply by whether or not certain objectives are met. Curriculum-based assessments and some classroom quality observations are examples of these kinds of assessments. Criterion-referenced assessments provide scores that are intended to be compared to a set of standards or objectives. A criterion-referenced test would indicate which children in a class mastered each particular skill or concept. Thus, criterion-referenced tests usually categorize children into groups—those who have mastered the material and those who have not, and sometimes those who are performing ahead of expectations. Interpretation can lead to insight when teacher or program goals are compared to the met and unmet criteria, with goals driving attention.

Classroom Quality Assessments

In the same way that child assessments are to be used to make better decisions about teaching and

caring for children, classroom quality observations can serve the same purpose. They resemble criterion-referenced assessments, as observers will look for evidence of certain aspects of quality.

Observational assessments such as the Environment Rating Scales (ERS) and the Classroom Assessment Scoring Systems (CLASS) are common measures. Higher scores are generally indicative of environments and interactions that are better for children, while lower scores may be indicative of unacceptable environments and interactions with children. However, some research indicates ceiling threshold of quality, above which the relationship to child benefits is not observed. Additionally, some items and scales are typically low, which could be an aspect of quality or an issue with the measure. Thresholds and low variability in the scales need to be investigated further to better inform programs about the usefulness of the scales. Until then, interpretation should be cautious and related to the stated purpose of the measures.

Both the ERS and CLASS family of observations are broken down into subscales, measuring various aspects of structural and process quality. Insights from these observational measures can be gained by examining the pattern of scores across the subscales. If the content of the subscales match goals of the teacher or program, these may be areas of focus for interpretation.

IPA/USA AMERICAN ASSOCIATION FOR THE CHILD'S RIGHT TO PLAY

IPA/USA is the American affiliate of the International Play Association. The purpose of the organization, founded in 1961 in Denmark, is to protect, preserve, and promote play as a fundamental right for all humans. The ideas behind the organization date back over 90 years to when Save the Children founder Eglantyne Jebb drafted the Declaration of the Rights of the Child in 1923. An expanded version of this proclamation was adopted by the United Nations General Assembly on November 20, 1959, as the Declaration of the Rights of the Child, which added five more principles to make 10

principles. Principle 9 of the 1959 Declaration of Rights addresses the child's right for "full opportunity to play and recreation" (UNICEF, n.d.). In addition, November 20 was adopted as the Universal Children's Day.

Interest in providing quality play opportunities for children had been gradually increasing over the decades before the signing of the Declaration of the Rights of the Child, and in 1955 a major seminar on playgrounds was held in Europe. The need for international action was evident, leading to the formation of IPA, which held its first conference in Copenhagen in 1961. Since then it has held 18 other international conference and plans to hold its 2017 conference in Calgary, Alberta, Canada.

The United Nations International Year of the Child in 1979 injected IPA with new energy. IPA originally emphasized adventure playgrounds, but gradually changed its focus to play itself and to the child's right to play. In the 1980s, IPA played a role in making sure the word *play* was included in Article 31 of the UN Convention on the Rights of the Child, which strengthened the Declaration of Rights of 1959.

In 1989, the Convention on the Rights of the Child (CRC) was adopted by the UN General Assembly, and it went into force the following year in the countries that agreed to be bound by its terms. As of October 1, 2015, when Somalia ratified the CRC, the United States remained the only country that had not ratified it. The Convention consists of 54 articles that address the basic human rights entitled by children around the globe. Article 31 specifically addresses the child's right to play:

1. States Parties recognize the right of the child to rest and leisure, to engage in play and recreational activities appropriate to the age of the child and to participate freely in cultural life and the arts.
2. States Parties shall respect and promote the right of the child to participate fully in cultural and artistic life and shall encourage the provision of appropriate and equal opportunities for cultural, artistic, recreational and leisure activity. (OHCHR, n.d.)

The American Association for the Child's Right to Play (IPA/USA) was formed in Philadelphia in 1973 as the U.S. affiliate of the international organization. The beginnings of IPA/USA started with playground creator and author Paul Hogan's 1967 trip to Europe. Hogan was checking out adventure playgrounds in London with Lady Allen of Hurtwood (founder of the World Organization for Early Childhood Education, known by its French acronym, OMEP) when he first learned about IPA and began attending its meetings. The United States had IPA members before the affiliate was formed by Hogan. Mrs. Thomas Hess of Greenwich, Connecticut, was the first American member, and Pacific Oaks College and Children's School in Pasadena, California, was the first American organizational member, having joined in 1969.

By the early 1970s, IPA/USA membership had grown to the point that a national representative was selected to send to IPA World Council meetings held at the triennial IPA meetings. The first U.S. representative was Paul Hogan, who attended the 1975 Milan meeting 2 years after IPA/USA was formed. The first president of IPA/USA was not "elected." While attending that 1975 conference, Hogan met Muriel Otter, the IPA secretary, and she declared that he would be president of IPA/USA. Hogan consequently started *PlayPlans* magazine and began to secure subscribers and more members for IPA/USA.

Elaine Ostroff followed Hogan as the U.S. representative to the international conferences. Donna Seline attended the Ottawa IPA conference in 1978 and was appointed U.S. national representative by IPA President Polly Hill of Canada. Seline organized a regional IPA/USA conference in 1980 at the University of Minnesota with keynote speakers Hill and Brian Sutton-Smith. A subsequent national IPA/USA conference was held in 1983 at the University of Minnesota with keynote speakers Janet McLean and Joe Frost.

In June 1983, the International Conference on Play and Play Environments—sponsored by IPA/USA and 12 other state, national, and international organizations—was held at the University of Texas at Austin. This was reputed to be the

largest gathering of play scholars ever convened, with more than 500 participants from 12 nations. At this conference, plans were initiated for a more formal organization of IPA/USA and for the 1986 national conference in Cincinnati. In July 1985, Seline submitted her resignation as national representative, effective April 1986.

In February 1986, Seline initiated calls for nominations for a formal board of directors for IPA/USA and a mail election was held. Elected for 2-year terms were Frost (president and U.S. representative), Sue Wortham (treasurer and membership coordinator), Marcy Guddemi (newsletter editor), and board members Jay Beckwith, Harris Forusz, Roger Hart, Robin Moore, and Barbara Sampson.

A USA/IPA national conference was organized by Forusz in 1986 and was hosted by Adventure Playgrounds, Inc. and the University of Cincinnati. Formal resolutions were agreed upon, including a pronouncement of support for the IPA 1977 Declaration of the Child's Right to Play, adopted in Malta in 1977 and revised in Vienna in 1982. Additional details for modifying incorporation and bylaws documents were addressed. Moore and Frost participated in the 1986 World Council IPA meeting and special International Year of Peace seminar in Birmingham, England. During this period a number of adventure playgrounds were developed in the United States. By 1987, IPA included members from 50 countries.

Thirty-five Americans attended the 1987 World Congress in Stockholm. By 1988 IPA/USA membership had grown to 165. In 1988 Tom Jambor was elected president and in that year the national conference was held in Washington, D.C., directed by Barbara Sampson, Moore, and Seline. Board members were Jambor (president), Stapel (treasurer), Guddemi (newsletter editor), and board members Duraid Da'as, Robin Epstein, Forusz, Hogan, Lulu King, Mary Lillie, Ruth Morrison, Jack Pentes, Donna Seline, Randy Smith, Frank Rudloff, and William Weisz. In January 1989, this expanded board met in Cincinnati and made plans for expanding revenue, the newsletter, and membership, and creating a clearinghouse on information. At the Tokyo conference in 1990, Moore of

IPA/USA, already an IPA international officer, was the first American to be elected IPA president.

With these patterns in place, IPA/USA programs continued to expand to the present time and include community PlayDays, annual play advocacy presentations at national conferences, semianual national IPA/USA conferences, promoting the international IPA conference, preparing and distributing materials for parents and school administrators promoting advocacy for and reinstatement of school recess, media campaigns for recess and outdoor play, and multiple efforts to support and gain awareness of the value of play and the child's right to play. National conferences were held jointly with the Association for the Study of Play at the Strong Museum of Play in 2007, Georgia State University in 2010, and Clemson University in 2013.

Membership in IPA/USA is open to any individual, group, or organization that endorses the right of children to play, stated in the 1959 Declaration of the Rights of the Child and in the 1989 Convention on the Rights of the Child. IPA/USA holds a national conference every 3 years and sponsors or cosponsors workshops and symposia from time to time. The *IPA/USA eJournal*, available on the IPA/USA website, is a peer-reviewed publication that features articles on play environments, safety,

toys and materials, play leadership, and the role of play in child development. IPA publishes an international journal called *PlayRights* and hosts a World Conference every 3 years.

J

JOYFUL LEARNING

Educators, developmental psychologists, and philosophers all describe a process that contemporary educators refer to as joyful learning. Socrates in his “questioning method,” Piaget’s “assimilation and accommodation,” Montessori’s reference to “normalization,” Dewey’s emphasis on experiential learning, and Csikszentmihalyi’s description of “flow” all give us insight into the phenomenon of joyful learning. For young children, joyful learning is facilitated by those teaching from a perspective of constructivism—believing that “children construct knowledge through interaction between their own ideas and experiences in the social and physical world” (Chaille, 2008, p. 5). Joyful learning experiences support the child’s growth both socially and cognitively.

According to Ward and Dahlmeier, joyful learning is a process that requires effort and includes making choices and making connections. Montessori refers to this effort resulting in joy when she describes a child as “one guided by his inward teacher, who labors indefatigably in joy and happiness” (1949/1994, p. 8)—a process she referred to as normalization.

Joyful learning has three essential components: engagement, exploration and discovery, and ownership. All three phases are critical in the joyful learning process. An activity might be classified as

“fun” and might be engaging, but unless the other two phases of the process are present, the fun is fleeting and the learning not enduring. Children may find watching a puppet show amusing and entertaining, but to invite joyful learning, the children would need to participate in creating puppets and producing their own show. A child might enjoy listening to a story, but to be a joyful learning experience, she needs to be involved in exploring the story, often through dialogic reading or shared reading. Finally, the child experiences ownership of the story through selection of the book as a play object, role-play reading, or returning to favorite pages. Part of the ownership phase is making future choices. The child, having had a positive, repetitive learning experience with this book, will choose another one.

Joyful learning can occur at any phase of development. According to Lewis (as cited by Ward & Dahlmeier, 2011, p. 95), “Joy is seen under two conditions by the middle of the first year: when the child comes in contact with a significant social other and when the child is able to demonstrate mastery over particular events.” Piaget described the learning mastery process of infants as circular reactions. As infants develop, they progress from repeating an accidentally discovered connection to their own bodies (such as kicking) to repeating an action on an object they have encountered accidentally (such as batting a rattle) to coordinating movement to repeat and vary the experience. A

child displays this example of joyful learning by repeatedly pushing a toy car across varied surfaces, expressing delight when it skids rapidly across a wooden floor. For the child in the preoperational phase, development and refinement of schema represent the third phase of joyful learning.

Vygotsky, also a constructivist, noted the importance of sociability in many joyful learning experiences. The infant who mirrors a smiling face and then later shows expressions of delight when she sees her special caregiver shows joyful learning. The child who observes and participates in an activity that offers an obtainable challenge and then explores until he, too, is able to complete this task is experiencing joyful learning in a social context.

Joyful learning experiences in classrooms involve a journey that the teacher and child share. Both are teachers and both are learners. For those teachers who establish a classroom for joyful learning, the explorations change year by year as the children take ownership. Their unique interests and experiences change the class. The teacher is the guide, responding to and enriching teachable moments and emerging interests. Inquiries and projects are undertaken in classrooms that inspire joyful, child-centered learning. For example, in Gina's early childhood class, the children decided to study whales after learning that classmate Harrison from Australia had seen whales. They created a life-size whale in the playground, then went on to study multiple sea creatures. The learning of these 5- to 6-year-old children was enhanced by the multiple connections they made—math in measuring the whale, language in speaking and writing about the sea and in using resources to find answers to their questions, biology as they explored the characteristics of land versus sea mammals and life cycles of whales, geography as they located areas of the world where one might see whales, and art as they created a whale and a sea mural.

Early childhood educator and author Mimi Brodsky Chenfeld similarly describes a preschool where the teachers and children dug a large hole for a to-be-delivered boat donated as a play environment. The discovery and learning that occurred

in the process led to a commitment to dig another hole to explore. The learning included language from conversation and new vocabulary, mathematical measuring, comparison and counting as treasures were unearthed, biology as creatures were discovered, geography as children mapped their imagined cities in the hole, and physical science as they noted the effects of rain and snow.

Both studies are examples of inquiry-based learning with the interest emerging from the children and the teachers enhancing the environment to maximize engagement, discovery, and ultimately ownership and reflection. The teachers did not control the learning, but rather facilitated the learning contributing to the joy of the process. Katz and Chard (2000) and Helm and Katz (2010) as well as proponents of the Reggio Emilia approach identify three phases of projects that align with our joyful learning phases. First is *getting started*, which equates with engagement, motivation, and in this case choosing a topic to explore in depth. Second is *field work*, which is a form of exploration of the topic. Finally is the *culminating event* and debriefing, which is the time for metacognition and reflection. This is the phase when the child takes ownership of her learning and makes choices for future learning.

Joyful learning experiences help children connect knowledge and skills, involve them in purposeful and active learning with choice, and connect children to their world. This learning might be through collaborative projects but can also be experienced individually. To support this learning, teachers and parents need to support children's choices and respect their individual rhythms and temperaments, give children time to explore their interests in a safe and nurturing environment, encourage discovery, and maintain dialogue among all members of the learning community.

K

KEY WORDS

Sylvia Ashton-Warner's method of teaching beginning reading in English is used in many of the countries where English is spoken, especially when English is the child's second language. Ashton-Warner (1908–1984) was a White (*Pakeha*) New Zealand (*Aotearoa*) teacher who taught 4- and 5-year-old Maori children in a segregated school system in the 1930s, 1940s, and 1950s. Her most memorable contribution was Key Words, also called Organic Reading or Key Vocabulary. She first wrote about the method in her semi-autobiographical novel *Spinster* (1959) and chronicled it again in her educational book *Teacher* (1973); both were bestsellers.

The Key Words method begins most simply: Words are kept in envelopes with the children's names on them. The first lesson begins with the child the teacher has chosen for his or her exceptional interest in words picking his or her envelope out of a spread of three or four envelopes.

Teacher and child sit together (child on right-handed teacher's left, or on left-handed teacher's right, so child can see clearly what teacher is writing) and they talk. They are seeking, jointly, to find a word that is vital to the child, one that represents something important. Ashton-Warner often said these words come from sex and fear. When teacher and child agree that a word is the right one, the

teacher writes it on a card. Some examples: *mommy, daddy, monster, perfume, money*.

The teacher hands the card to the child, "I'm giving you *mommy*," asks the child to trace the writing on the card with his or her finger, makes sure the child knows what this word is, and then she hides the word in the deck of the child's cards. (At the first lesson she mixes up the new word with the envelope, which says the child's name . . . presto, two words.)

A day or two (but no longer) after the first lesson, the teacher reviews the words (child's name and *mommy*). If this child tends to be unfocused the teacher can remark, before asking the child to read them, "Yesterday I gave you a new word, *mommy*, and you already could read your name." One new word is given per day, but the word may be compound or two or three words (e.g., *sparkly ring* or *fancy pink dress*). The child will know the words (or the whole phrase). So the teacher can say, "You know your words, so you can have a new one."

To find the next new word, another discussion takes place. Remember, a key word is one both the child *and* the teacher think matters. As the child becomes familiar with this work, often he or she will run to the teacher, knowing what word *must* be given today. It is rare that the word is one like *chair* or *nose*, but often these will be words like *ice cream* or *baseball*.

The teacher shuffles the cards often, making sure that the words are *recognized*, not *remembered in sequence*. Some teachers have made the

error of putting cards on a ring, but that means that a child can learn that *mommy* follows *grandma*, instead of recognizing the configuration of letters and shapes.

The other children have seen this work and ask to do it themselves. The teacher keeps a list and calls them to him or her in sequence. By the fourth week (sooner with older children) all the children have joined in the work.

After each lesson the teacher puts the child's new word in a basket so that later in the day the children, sitting in a circle, read the new words to each other and tell important things about their new words, and then the words will be returned to the envelopes. This leads children to request words their friends have.

Any word a child can read can be put on a card and put into the envelope. At some point in the school year many children will be able to read all the names of the other children, having seen them on paintings and cubbies and so forth. This makes for a thick, satisfying envelope, proving to the children that they are gaining lots of words.

The method calls for lessons using this practice at least three times a week, but preferably every day. As lessons go on, there will be the occasional word that the child forgets. The teacher can ask, "Do you want to learn it or throw it away?" indicating by her tone of voice that there is *nothing wrong with* throwing a word away. Depending on the child's reply, they can practice hiding the word in the deck and finding it, or the child can put the card in the trash. If this is handled nonjudgmentally, the child continues to have an envelope with words that are powerful and meaningful to him or her. No words the child can't recognize should be in his or her envelope.

After the child has a fair number of words (maybe 15 or 20) the teacher can supply a verb. So, if the child has many people's names, the teacher gives *loves* or *likes* and then sets the words on the table so the child can read the three-word sentences that follow: *Jimmy loves mama; mama loves Jimmy*, etc. The reader who wants to go beyond this first experience of Key Words is advised to read Katie Johnson's *Doing Words*.

At the time Ashton-Warner was teaching in the Maori schools, the objective seemed to be to make White children out of the Maoris. Maori culture, history, and values were not part of the curriculum. Ashton-Warner had difficulty working under these conditions. She developed her method after failing to get the Maori children to read with the imported *Janet and John* books, which assumed a child familiar with trains and watering cans, not a child in the bush who knew canoes and horses. This made for a huge disconnect between the children and learning to read. Ashton-Warner reflected upon what she saw in her early childhood classroom: bright, communicative children who felt no connection to the bloodless vocabulary of these primers that had no content nor style nor rhythm that was artful or appealing. What these children cared about was relationship and story. The children's first language was Maori, and the *Janet and John* reading books were not only in English, but English from far-off England, halfway around the world (and they were revisions of American books!).

Ashton-Warner recognized and respected the individuality and creativity of the children. "The only time they show any sign of interest is when I let them draw" (Ashton-Warner, 1969, p. 35). Ashton-Warner found that if a personal set of words was chosen collaboratively by teacher and child, one word at a time, these un-illustrated words that name the pictures in the child's heart would be learned easily and stay learned. They are words of fear and of love, names of both the beloved and the scary beings that populate the child's imagination. The teacher and the child meet privately (amid the bustle of the primary classroom) and together find the word: *ghost, mommy, hot sauce, monster, perfume, or money*, which the teacher writes on a stiff card and puts in an envelope with the child's name on it. Over time, one word a day, the child collects his or her words.

A research study was conducted by Selma Wassermann, in 1971, when Ashton-Warner was teaching with Wassermann at Simon Fraser College in Vancouver, British Columbia. It found that children in the experimental and control groups

showed equal skills acquisition on the standardized tests used at that time and in that place. But the group studying key vocabulary and the control group exhibited substantial differences in a sentence-completion task, where the control group of 19 children reported themselves as readers finishing the sentence “When I read I . . .”

Eight completed the sentence with “read with my eyes,” two with “read quietly,” and two simply with “read.” One each completed the sentence with “read when my mother tells me to,” “read nice,” “will read,” “read science books,” “take a book,” “I don’t like it,” and “read in my mind.”

The experimental group of 24 children (whose teachers had been learning from Ashton-Warner) had different answers:

Seven completed the sentence with “feel happy.” And one each “I like reading the whole book,” “read it to the teacher,” “feel mad,” “am glad to read,” “read it carefully,” “feel okay,” “feel sad,” “I say good,” “read to my friend and my auntie,” “read a book,” “feel good,” “am very happy,” “read and after I finish I think of the story,” “am sad because sometimes I don’t know a word,” and “get my book and read.”

So children taught Key Words were as good readers as those taught in the look-say method in use at that time, but the Key Words group *loved reading more*.

Many schools now emphasize phonics, or the systematic instruction on the spelling of various sounds, in early reading instruction. In part because of the irregular spelling and sound relationships in English, proponents of the Key Words approach see this as setting children up to fail. The constructivist nature of Key Words, emphasizing words that name things of interest to the child rather than sound-symbol relations, makes finding meaning the goal of reading instruction. Key Words advocates are convinced that this way of learning is supportive and positive, with children taking the lead in vocabulary, and becoming skillful. Social and education critic Paul Goodman wrote:

Consider . . . the method employed by Sylvia Ashton-Warner in teaching little Maoris. She gets

them to ask for their own words, the particular gut-word of fear, lust, or despair that is obsessing the child that day; this is written for him on strong cardboard; he learns it instantaneously and never forgets it; and soon he has an exciting, if odd, vocabulary. From the beginning, writing is by demand, practical, magical; and of course it is simply an extension of speech—it is the best and strongest speech, as writing should be. What is read is what somebody is importantly trying to tell. (Goodman, 1964, p. 26)

Teacher and Spinster, Ashton-Warner’s books about reading, have been translated into many languages. In former British colonies that have become independent (but still speak English), teachers find they can use Key Words to help children into reading. Children whose native language is English also can be taught using the Key Words method.

Another argument is over the role of the New Zealand educational system. Did the country’s Department of Education make Ashton-Warner’s contributions possible? That contradicts Ashton-Warner’s own statements, in several of her books, that she went unrecognized and unappreciated in her country for most of her life. Not a few people in New Zealand have dismissed Ashton-Warner’s work, saying, “All of us taught like that in the 1940s.” Yet despite the emphasis of the Education Department on Herbert Read’s arts-focused writing, we see little evidence of teachers supporting Read’s advocacy and descriptions of “creative surge” and none supporting creative reading, other than Elwyn Richardson’s documentation of his teaching Maori children through art.

The historical facts are in dispute, but clearly and profoundly, Ashton-Warner’s contributions to the many children who learned, seamlessly, to understand what reading is about, how it can name their passions, and that they *are* readers, came from her work with Key Words.

been extensive debates about its goals and the most appropriate pedagogical approach for achieving those goals. While play and social skill development are seen by many as the original objectives of kindergarten, over the past century there have been repeated calls to more explicitly focus early childhood education on academic instruction as a strategy to improve schooling outcomes.

Since the late 1990s, kindergarten classrooms have indeed been characterized by a heightened focus on academic skill building, and particularly literacy instruction, in kindergarten classrooms. These changes, many posit, have been driven by the introduction of high-stakes accountability systems in K–12 schools as well as the broad introduction of early learning standards. Critics worry the increased focus on academic instruction is developmentally inappropriate and crowds out other important early learning experiences. Proponents, on the other hand, suggest academic instruction in early schooling can yield important benefits for children and narrow socioeconomic achievement gaps when taught in an engaging, age-appropriate way.

This entry describes the typical kindergarten experience in the United States today and highlights key ways in which kindergarten has evolved. It then summarizes the arguments and evidence surrounding new trends in kindergarten practices.

KINDERGARTEN

Children's experiences during their first years of formal schooling have an immense impact on their developmental trajectories as well as longer-term adult outcomes such as college participation and earnings (Chetty et al., 2011). Historically, kindergarten marked the beginning of children's formal schooling experience. The first kindergartens appeared in the United States in the 1850s, and were heavily inspired by German educator Friedrich Froebel's model, which focused on discovery, play, and social interactions. For nearly as long as kindergarten has existed, however, there have

Kindergarten Classrooms Today

Trends in Kindergarten Enrollment

Kindergarten attendance in the United States is nearly ubiquitous. Only eight states *require* 5-year-olds to enroll in school and just 15 states mandate that children attend kindergarten prior to starting first grade, according to 2014 reports from the Education Commission of the States. Nevertheless, nearly all children now attend kindergarten in the year prior to first grade. In 2013, for example, 70% of 5-year-olds and 20% of 6-year-olds were enrolled in kindergarten, according to the U.S. Census Bureau. This high participation rate reflects a massive expansion in kindergarten enrollment

since the middle of the century. Between 1935 and 1986, every state in the country began providing some publicly funded kindergarten and over time states' investments in kindergarten has expanded (Cascio, 2009; Dhuey, 2011). Overall, kindergarten enrollment in the United States increased from roughly 1.6 million in 1955 to 4.3 million in 2013, according to the Census Bureau.

Not only has overall participation in kindergarten grown drastically, but the *dosage* of the kindergarten experience has also increased. In 1998, just over half of kindergarteners attended a full-day program. By 2010, this figure had grown to 80%.

For most children in the United States, kindergarten is no longer the first formal classroom experience. Between 1970 and 2013, the number of U.S. 3- through 5-year-olds enrolled in nursery school or preschool (but not kindergarten) more than quadrupled, from 1.1 million to 4.7 million. The majority of those preschool slots are publicly funded, and oftentimes located inside elementary school buildings.

To summarize, the prevalence of kindergarten has changed substantially in recent decades. Whereas kindergarten was once a part-day, often-targeted program that served as children's first transition into a classroom setting, today nearly all children in the United States attend kindergarten, most do so full-time, and for many, kindergarten now serves as the second or even third year of formal classroom learning. There is now compelling evidence that the expansion of kindergarten led to positive benefits for children as well as increases in maternal employment.

Inside the Kindergarten Classroom

In addition to the increases in enrollment and duration, there has also been a distinct shift within kindergarten classrooms, away from the initial focus on play and socialization. Large observational studies collected in the mid-1990s and early 2000s of kindergarten classrooms across the United States provide telling windows into the typical day in the life of a kindergartener. These studies showed roughly 28% of the kindergarten day was devoted to literacy instruction, compared to

11% to math, 9% to science and social studies combined, and 9% to art and music. Further, most of the kindergarten day was spent on teacher-directed whole class or individual instruction (37% and 20%, respectively) with relatively little time devoted to child-selected activities (6%) (LaParo et al., 2009; Pianta, La Paro, Payne, Cox, & Bradley, 2002).

Recent work leveraging two nationally representative datasets from 1998 and 2010 demonstrates that the emphasis on literacy as well as the use of teacher-directed instruction in kindergarten is on the rise. Bassok, Latham, and Rorem (2015) showed that over this period teachers' expectations for incoming kindergarteners with respect to academic skills (e.g., letter and number recognition) rose drastically. Relatedly, while only 30% of kindergarten teachers in 1998 believed children should learn to read while in kindergarten, this number rose to 80% in 2010. The authors also demonstrated substantial increases in time spent on advanced literacy and mathematics skills concomitant with large drops in time devoted to science, music, and art. Furthermore, the percentage of classrooms that spent 3 or more hours in teacher-directed, whole-group instruction more than doubled, from 15% to 32%; time spent using textbooks, workbooks, and worksheets also increased substantially. Finally, the authors showed a substantial increase in standardized testing in early childhood settings. Specifically, in 1999 only 11% of *first-grade* teachers reported using standardized tests at least once a month. By 2010, 29% of kindergarten teachers reported assessing children using state or local standardized tests at least monthly.

Debating the New Kindergarten

The changing nature of kindergarten—particularly the heightened focus on academic skill building and teacher-directed instruction—has been extensively criticized by researchers and practitioners. One concern is that a heightened focus on academics could be stressful for children and negatively impact their self-confidence and attitudes toward school. Another is that the focus on

academic instruction could crowd out other types of valuable learning experiences critical to the development of children's social-emotional and physical well-being. Nobel laureate James Heckman argues the emphasis on academic skill building in early education is misplaced because the long-term benefits of early schooling operate through impacts on noncognitive social and behavioral skill building, rather than academic skill building.

On the other hand, there are a number of reasons an emphasis on academic content in kindergarten (and particularly on engaging, advanced content) may be beneficial for young children. First, a number of studies have now demonstrated that children's early *academic skills* are far stronger predictors of later-life outcomes than are children's social skills (Duncan et al., 2007). It may be the case then that early investments in academic instruction set children on a higher learning trajectory and allow low-income children to catch up with higher-income peers who are more regularly exposed to literacy and numeracy in their home environment. Magnuson, Ruhm, and Waldfogel (2007), for example, showed that more academically oriented early elementary experiences helped children who did not attend preschool catch up with their peers.

It may also be the case that due to the rapid expansion of preschool programs, children today are entering kindergarten having mastered skills that were once under the purview of kindergarten teachers. Indeed, kindergarten teachers in 2010 reported that children—particularly those who were low-income and members of racial/ethnic minorities—entered kindergarten with much higher literacy and math skills than in 1998 (Basok & Latham, 2014). Relatedly, two recent studies leveraging nationally representative samples of kindergarteners showed teachers allocated most of their mathematics instruction to basic skills such as counting and shape identification, despite the fact that the vast majority of children had already demonstrated mastery of those topics (Engel, Claessens, & Finch, 2013; Engel, Claessens, Watts, & Farkas, 2015). Further, time spent on this duplicative content was negatively associated with

children's kindergarten learning, whereas time spent on more advanced content was generally linked to positive gains.

Conclusion

Although debates about the goals of kindergarten are not new, the marked changes to kindergarten since the late 1990s, as well as the recent roll-out of the Common Core State Standards for kindergarten, have led to particularly charged critiques (and defenses) of kindergarten. At their core, these are debates about *what* and *how* kindergarteners should be taught. Should the focus be on basic skills and academic learning or creativity and unstructured play? Should instruction be directed by the teacher or child centered and inquiry based? Framing kindergarten instruction as a choice between “developmentally appropriate” and “playful” experiences on one hand, and “academic” and “didactic” instruction sets up a false dichotomy.

It is important to distinguish between *what* is being taught to young children and *how* it is taught. Oftentimes academic instruction is assumed to occur in classrooms that are more teacher directed and less playful. Many critiques of early academic instruction are more concerned with over-reliance on worksheets and rote tasks than exposure to early literacy and numeracy experiences, per se.

In recent years, developmental scientists and the National Association for the Education of Young Children have moved away from the position that early academic instruction is inherently developmentally inappropriate. Rather, they make the case that the benefits of such instruction are inextricably linked to the pedagogical approach, the quality of teaching, and the connection between instruction and young children's curiosity (Katz, 2015; Snow & Pizzolongo, 2014). However, the instruction needed to effectively facilitate this type of learning environment—one that relies on a nuanced understanding of pedagogy, subject matter, child development, and sensitivity to teacher-child relationships—is not the status quo in today's kindergarten classrooms. As kindergarten continues

to evolve, finding ways to invest in the training and support of teachers who can provide young children with playful, engaging, supportive, *and* challenging instruction is a top priority.

KINDERGARTEN ENVIRONMENTS

Kindergarten is a place for young children to socialize with other children and gain an understanding of school routine, and kindergarten is a place where young children learn. The kindergarten environment provides the stage where this all happens. The teacher is the director who, along with the children, creates a place for learning and a place for socializing. The kindergarten environment is a powerful and important teaching and learning tool. If the kindergarten environment is thoughtfully designed and structured, much of the

work of the kindergarten teacher is done even before the children arrive.

Kindergarten children learn by being actively engaged in activities with materials that are meaningful to their life experiences. Creating learning environments in kindergarten that are responsive to and recognize the developmental characteristics of children at this age will result in optimal learning experiences. As the school year progresses, the kindergarten learning environment should change to reflect the developmental changes that occur in children as they mature and gain new experiences. Responsive and welcoming environments promote kindergarten children's socialization, exploration, communication, curiosity, and creativity. In addition, skillfully designed and structured kindergarten learning environments support children's development in all domains—cognitive, language, social, emotional, and physical development. Kindergarten learning environments that foster both learning and development in ways that are appropriate for children's level of receptiveness also create in children a positive disposition toward learning and a sense of belonging.

Creating Kindergarten Learning Environments

Creating kindergarten learning environments is much more than simple room arrangement. Kindergarten learning environments should include both indoor and outdoor spaces and resources. Learning environments that are both dynamic and stimulating will fulfill the following functions in the kindergarten classroom, for children, and for teachers:

- Facilitate and guide children's activities, play, discovery, and exploration as vital processes in enhancing children's development and learning in all areas.
- Advance the holistic character of children's learning and development in an environment that stimulates exploration, investigation, curiosity, creativity, and socialization.
- Promote and encourage children's independence and sense of responsibility.
- Positively encourage children's participation with the family and in the community.

Indoor Kindergarten Learning Environments

Indoor or classroom learning environments receive the most attention from kindergarten teachers, from children, and from parents. The classroom is oftentimes the initial impression people have of the nature of learning environments in kindergarten. The manner in which the classroom environment is designed and structured reflects the values and philosophy underlying the learning that is to take place in that space. A number of different learning areas are appropriate for the kindergarten classroom environment. It is important to note that some of these areas will remain constant throughout the school year, while others will change as themes, children, or teaching and learning needs change.

While each of these areas has qualities that are unique to the area, there are also some qualities that are similar across the learning areas. In all of the learning areas children should have opportunities to experiment, explore, problem solve, be creative, and engage in learning processes that are active as well as both teacher directed and child directed. Children should have opportunities for choice (within a structure that the teacher has created). The activities and materials should be concrete and relevant to the life experiences of the children in the class; they should be open ended yet purposeful. The following areas are suggested to be part of a dynamic and purposive kindergarten learning environment.

Large Group Area. This is the area in the classroom where children meet as a group during different times of the day. It is the area in which large-group instruction occurs, where listening and sharing occur, and a general place for gathering the whole class together for various purposes. It may also be the place where children share literacy experiences with the class as a whole.

Language and Literacy Area. In this area of the classroom children have the opportunity to choose from among a variety of reading, writing, and language activities. It is a place where children can

experiment with print materials as well as have access to familiar books, magazines, and newspapers. Children should be given the opportunity to engage in reading and writing experiences either alone or with another classmate. It is also a place where children can experiment with a variety of writing implements, using these implements to create stories and pictures. This area is also rich in opportunities to develop language and listening skills. Recordings of books are provided so that children can listen to stories while following along with the print materials.

Manipulative Area. In this area, children are provided with a variety of manipulatives, games, and materials that are used primarily for the promotion of mathematical learning. In the manipulative area, children can count objects, sort objects, compare quantities, and measure objects. This area should be large enough so that more than one child can work independently or for more than one child to work cooperatively.

Inquiry Area. The inquiry area is a place where children can use all of their senses in activities and with materials that will enhance their understanding of scientific knowledge. It is an area in which children can explore, experiment, manipulate, discover, and observe. In this area it is important to create an environment in which children can construct their own knowledge and their own learning through active exploration and experimentation with the materials that are provided. This is the area in which the classroom pet may reside, as the experiences that children have with live animals and insects in the classroom are also an integral part of the inquiry process.

Technology Area. In this area of the room, children are provided with materials that will enhance their use of technology as a means of augmenting learning in any or all of the curriculum content areas. It is important to note that for the use of technology to be effective, it should be developmentally appropriate, encourage creativity and independence, and be integrated with curriculum outcomes. Computers along with software and websites that

are carefully chosen can do much to extend learning for children. The use of digital cameras and/or a tape recorder will be useful in facilitating children's documentation of their own learning.

Expressive Arts Area. This is an area of the room that is designed to allow children to express themselves creatively through various modalities. Children should be encouraged to express themselves creatively through art using different media. Children should also be provided with space to express themselves creatively through dramatic play. Dramatic play provides children with the opportunity to interact, experience, and re-create actual or imagined situations. It is an opportunity for children to try new things without fear of failure, as there are no external standards for accomplishment.

Block/Construction Area. Building with blocks or constructing with other materials gives children the experience of developing mathematical and scientific concepts such as size, shape, number, and quantity. In addition, children will gain a sense of what balance means, or what it means for a structure to be symmetric. Activities in this areas also develop children's ability to problem solve and engage in social learning in ways that are meaningful to them.

The kindergarten classroom schedule is a critical component of the learning environment. The daily schedule should be one that is consistent and one that offers plenty of time for children to engage in the learning activities that are offered to them within the context of the kindergarten environment. While the schedule should be consistent, it should also be flexible so that the number of transitions that children experience is kept to a minimum. Establishing classroom routines will provide the children with the security of knowing what to expect, therefore creating a learning atmosphere where the potential of classroom spaces can be maximized.

Kindergarten children spend a lot of time in the kindergarten classroom, and as such, the classroom should be a place that is a comfortable place for children to learn and where they all feel valued. The classroom environment should be decorated

with original materials that are created by the children in the class. These could include artwork, stories, and projects. These materials could be created by individual children as well as by groups of children. There should be spaces where children can work alone or where they can work with other children. There should be quiet spaces and spaces where "noise" is an acceptable mode of learning.

Outdoor Kindergarten Learning Environments

The outdoor kindergarten learning environment can and should be an extension of the indoor learning environment. By engaging in various activities outdoors in areas that are well designed and structured and where materials are plentiful, learning opportunities will flourish. A well-planned outdoor learning environment will maximize the freedom of choice and independence of kindergarten children. It is critical that teachers continually assess the outdoor learning areas and make appropriate adjustments as necessary. Many of the same criteria that are used in designing indoor learning environments can be used when designing outdoor learning environments:

- The outdoor space should be large enough so the number of children and equipment can be accommodated.
- Supervision of children should be possible from any area.
- There should be a variety of age-appropriate materials and equipment.
- The outdoor area should be safe and protected from traffic.
- Accommodations for children with specific needs should be addressed when appropriate.

Final Considerations

Well-designed kindergarten environments are an integral component of the kindergarten curriculum—a component that facilitates learning and development, enhances learning and development, and creates opportunities for learning and development. As stated earlier, it's the stage on which

the teacher directs and provides structure to children's learning experiences. Kindergarten environments are both indoors and outdoors. Well-organized kindergarten environments, whether they are indoors or outdoors are

- welcoming and inviting to children;
- exciting, vibrant, flexible, yet dynamic;
- responsive to children's ever changing interests, needs, abilities, and developmental levels;
- spaces that invite making choices, social interactions, risk-taking, discovery, connections to nature, language, play, collaboration and cooperation;
- spaces that provide a sense of place and purpose;
- spaces that are plentiful with learning resources, materials, and experiences;
- consistent and predictable, yet flexible when needed;
- both interesting to children and engaging;
- spaces that provide children with complex and deep learning experiences (rather than shallow, meaningless, irrelevant, or superficial experiences);
- spaces that contain open-ended, complex, and interesting materials that can be used in many different ways and for many different purposes;
- spaces that provide children with materials and activities that can be experienced over and over again without becoming boring;
- spaces that provide a balance of experiences to children that facilitate learning across the curriculum and enhance development in all domains; and
- spaces that provide children with various types of experiences that can accommodate all learning styles, developmental needs, and individual differences.

In creating learning environments, kindergarten teachers are provided with ideas and strategies for enhancing the learning that occurs as children are engaged in curriculum activities. Teachers intentionally think about organizing the kindergarten environment (both indoors and outdoors) in ways that will provide children with meaningful and

accessible materials and activities. Environments that support all areas of development, are responsive to all children's pace of development and style of learning, and promote learning across the curriculum will encourage all kindergarten children to explore the many opportunities and possibilities for learning in a caring learning environment.

LANGUAGE DEVELOPMENT

During early childhood, children come to understand and produce the language or languages they are exposed to. This process is called language development. Language development is a multifaceted task that involves learning the repertoire of sounds of one's language (phonology), learning the vocabulary of one's language (lexicon), learning how to combine words together to create meaningful sentences (grammar), and learning how to communicate effectively with others using language (pragmatics). This entry focuses on typically developing children learning one first language, and highlights accomplishments in each area of language development across the early childhood period. It then discusses the close relationship between language and literacy development and the important role that parents and preschool teachers can play in children's language development.

Phonological Development

Phonological development concerns the child's acquisition of speech sounds. Every child is born with the ability to distinguish a full range of sounds and therefore to learn to understand and pronounce words in any language. This ability gets more limited the more the child is exposed to the specific sounds of their own language or languages. Indeed, as early

as 5 to 6 months of age children are already losing the ability to distinguish sounds in languages they are not exposed to, and are becoming experts at the sounds they are exposed to. Each language has its own repertoire of speech sounds or phonemes. Honing the ability to produce these phonemes accurately is the child's first step toward speaking a language.

Children make sounds from birth. Early sounds primarily consist of crying and burping, yet around 2 months of age children start cooing or producing drawn-out vowel sounds. Between 6 and 9 months, infants enter a stage called canonical babbling where they begin to pair consonants and vowels together (e.g., /dada/, /baba/) and exhibit some traits of adult word sounds and timing. Children continue to add phonemes to their babbling repertoire and around 10 months also begin to use conversational babbling (also known as jargon) where they can string a series of sounds and syllables together using adult-like cadence and timing. This ability to put syllables and sounds together demonstrates the child preparing for more fluent speech and for the role of conversing with another person.

Starting around 1 year of age, children begin to replace babbling with words. As their vocabulary expands their ability to produce all the phonemes in the language is still limited, thus they often simplify words to be able to pronounce them (e.g., saying "nana" for "banana"). This is due to ease of use and also due to physical and neurological

development where some sounds (e.g., “th” in “that”) are harder to produce when the child has less-developed motor skills to move their tongue accurately to form that sound. Children’s pronunciation of sounds continues to improve with practice and the development of their motor skills, and in response to input and feedback from parents and others. By the preschool years speech is much more intelligible, and by age 7 children are adult-like in their phonology.

Children’s phonological awareness is also important for literacy. That is, the more children understand about how to manipulate the phonemes in their language the better prepared they will be for learning to read. Examples of manipulating phonemes include being able to play rhyming games with words (what rhymes with “hat?”), and being able to produce words with and without certain sounds (e.g., say “cat” without the /c/ sound). These are excellent activities for preschool children to engage in to increase their phonological awareness.

Lexical Development

Although children do not typically begin speaking words until after their first birthday, they comprehend words early on in infancy. Lexical development is separated into two categories: receptive vocabulary, which relates to what words the child hears and can understand, and productive vocabulary, which relates to what words the child can produce himself or herself. Children have a much larger receptive vocabulary than productive vocabulary and thus can understand more words than they produce. Infants begin to show signs of understanding some basic words such as “mom” or “dad,” as well as their own name at approximately 5 months old. By 12 months when infants begin to produce their first words, they already have a good understanding of many words. For example, an infant with a receptive vocabulary of between 100 and 200 words will have a productive vocabulary of fewer than 50 words.

During the second year of life there is a great increase in receptive and productive vocabulary development. As children begin to build their early

vocabulary, nouns are usually acquired faster along with some key verbs. In fact on average, 40% of an English-speaking child’s first 50 words will be nouns. Children can acquire words very quickly. Sometimes only minimal exposures to words are necessary, a process known as fast mapping. For example, imagine a parent using the word “cat” while pointing at a cat in front of the child. The toddler may be able to retain the word after just a few instances of hearing the word coupled with the referent. However, while children are beginning to grasp these newly acquired words and their corresponding meanings (known as semantic development), they can still make some common errors. For example, children may over-extend the meaning of a certain word (e.g., learning the word for cat and applying it to a dog) because of the similarities between them. In some cases, children will know the meaning they want to convey and will “invent” a word in order to describe the concept (e.g., they might say “horse-house” instead of “stable”). Parent and preschool teacher input helps children hone these skills and continue to develop and expand their vocabulary. By the time children are in preschool they may have productive vocabularies of over 1,000 words, and after this point their vocabulary is growing by between 2,000 and 4,000 words per year.

Syntactic Development

In addition to learning words, children need to learn how to combine words together into sentences. One of the key skills required in this process is morphological awareness. Morphemes are the smallest unit of meaning in language and take the form of individual words (free morphemes, such as “book”) as well as additions to a word (bound morphemes). Bound morphemes can be derivational or inflectional. Derivational morphemes are additions that change the meaning of the word. For example, if you add morphemes to the word “employ” to create the words “employ-er,” “employ-ee,” “employ-s,” and “employ-ment,” each new word now has a different meaning. Inflectional morphemes, on the other hand, relate more to grammatical changes than changes in

meaning. These morphemes always take the form of suffixes and are applied when relevant to the grammatical context (e.g., “float” to “float-ed” or “join” to “join-ing”). These morphemes are necessary for children to master in order to learn to use correct grammar.

The order in which the most common morphemes are acquired is remarkably similar across different children. A famous study by Roger Brown found that, for example, the gerund (e.g., “playing,” “jumping”) is acquired earlier than the more complex auxiliary (e.g., “Daddy’s going dancing”). When a child begins to grasp the morphology of their language, they may make production errors that signal that they are learning the rules of their language. For example, in English there are many irregular verbs that are tricky for children and they often say things like “I goed” or “I falled.” These errors are often corrected by parents’ and teachers’ verbal responses “you went” or “you fell,” and children ultimately memorize the irregular forms.

The creation of novel sentences requires syntactic knowledge and is a most pivotal step in a child’s language development, as it allows the child to express himself or herself in novel ways, known as productivity. Each language has strict syntactic rules about how to form sentences, for example, English is an SVO language, meaning that sentences normally have a subject followed by a verb and followed by an object (e.g., Daisy loves painting). Well before they are able to produce meaningful sentences, children can comprehend the difference between the sound of grammatical and ungrammatical sentences (again, comprehension precedes production). Between 12 and 18 months, children will begin to use single words in a holophrastic way to express whole sentence meanings, for example, “bottle” to mean “Please give me my bottle.” Children then progress to two-word utterances, or telegraphic speech, between 18 and 24 months (e.g., saying “mommy tea” to depict the possessive “mommy’s tea” or “daddy play” to explain that “daddy is playing.” Between 24 and 36 months, children progress from combining the words they know into short utterances (e.g., “Mommy no come” to ask “Is mommy not coming with us?”), after which they progress to more

fully syntactical sentences. With practice, exposure, and feedback, eventually children’s morphological and syntactic awareness improves and they can create longer and more syntactically rich sentences and ultimately whole narratives.

Pragmatic Development

Part of becoming an effective communicator requires knowledge of how to use language appropriately in social contexts to serve different communicative functions or intents. Early communicative intents are evident in the first year of life in children’s use of the pointing gesture to request an object, or their use of babbling with intonation to ask a question. During the toddler and preschool years, children become more adept at taking turns in conversations and maintaining a conversational topic, yet conversational skills continue to grow throughout the early childhood period.

Sociolinguistic knowledge also falls under the realm of pragmatics. Examples of this are understanding culturally relevant rules of politeness and recognizing that different speakers might require a different type of language or discourse (e.g., how they speak to their peers as compared to a teacher). The development of conversational skills and social knowledge about language develops naturally over time with modeling from parents and teachers as well as exposure to different social environments (e.g., playing with peers on the swings as opposed to the doctor’s office). Children are typically still honing these skills early into their grade-school years.

Relation Between Language and Literacy Development

There are very clear links between oral language development and learning to read. Children who have stronger oral language skills when they arrive at kindergarten, on average, have an easier time learning to read and are more successful in school than children who start off with weaker oral language skills. This is not surprising, as the process of learning to read builds upon the linguistic

processes of language development already in place. For example, learning the sounds that correspond to specific letters and how to decode written words builds upon children's phonological awareness, or knowledge of the sounds in their language and how to manipulate them. Vocabulary is also key in literacy, since along with learning to decode written words, children need to know word meanings to comprehend the text. One way to foster language development during early childhood is to ensure that children are engaged in a lot of interesting conversations. Specifically, research shows positive oral language and literacy outcomes for children when their preschool teachers and parents talk to them a lot, use a large variety of vocabulary words, ask a lot of "why" or "how" questions, engage them in conversations about the non-present (e.g., something that happened last week), and talk about a wide variety of topics.

LANGUAGE DEVELOPMENT, THEORIES OF

Language is a great power—the major means of communicating—via conversations, wedding

toasts, books and magazines, legal briefs, prayers, text messages, Pinterest, Netflix, Twitter, Facebook, and other avenues ever expanding in the electronic world.

Theorists differ in their concepts with respect to various aspects of language. Some focus on sentence structure versus function. Some differ on the relationship between intelligence and thought as contrasted with language. Lev Vygotsky believed that language and thought both have roots in infant development. In contrast, Jean Piaget (1973) asserted that intelligence and thought develop *prior to* and outweigh language in importance: "Language appears at the same level of development as symbolic play, deferred imitation, and doubtless, mental image as interiorized imitation" (p. 117). Thus, for Piaget, thought is primary. Logical operations involved in combinatorial thinking and transformations involving "coordinating inversions and reciprocities . . . outdistance the subject's language and could not even be formulated with the sole aid of language" (p. 120). Piaget does acknowledge that for the child who has matured beyond the sensorimotor stage, language intertwines with thought and can facilitate more powerful thinking.

Developing language skills, whether receptive (understanding) or expressive (speaking), is a complex enterprise that must be mastered over many years. The three great streams of human language that children must become proficient at are speaking, writing, and reading.

Theorists attempting to make sense of language learning data have focused on different aspects of language acquisition. Infants use one-word *holophrastic* speech; older toddlers produce *telegraphic speech* with two- and three-word phrases ("Me like candy!"). M. D. S. Braine theorized that children innately possess a rule called *contextual generalization*. That is, having heard a word in a particular language context, a child will tend to use that word in the same position in another context. Thus, one 3-year-old, seeing a man standing on top of a hill and knowing his father loved climbing, called out "Papa!" to a startled stranger standing up there. Braine's theory posited toddler use of a frequent *pivot word* (supposed to occur

only in initial or final phrase position) combined with a less frequent *open class word* that tends to be a noun or verb: “More juice” or “Want dat.” Two-word phrases were never supposed to consist of two pivot words. However, language samples show that toddlers do combine two pivot words, as when a child wants her papa to give her another horsey ride: “Daddy more!” Some linguists, such as Roger Brown and Peter A. Reich, have divided toddler utterance into other categories such as assertions (“My sock!”), descriptions (“stove hot”; “doggie bad”), comments (“Big ball”), and requests (“Want dat”).

Language theories differ in whether they emphasize experiential/cultural or innate explanations for linguistic development. B. F. Skinner, eminent proponent of the power of operant conditioning, avoided “mentalistic” or innate conjectures and focused on language production rather than competence. He proposed that the same learning rules apply for *all* learning, including language. Children imitate adult models who reinforce and shape child verbal productions. However, data reveal that parents rarely correct toddler grammar. Instead, parents often praise a child for intent or content by saying “Right” as when a toddler correctly comments about the neighbor’s cat: “Nice kitty go meow.”

Language is far too complex to be simply learned only through adult shaping of child speech. Of course, to acquire spoken language facility, a child must hear and accurately produce the sounds and words of a language. Hearing children of non-verbal deaf parents do not learn language from watching television. A traumatized child or one who has speech dysfluencies may have low performance and yet possess much higher language competence.

Adult inputs surely do influence child language abilities. Genie, a girl raised in isolation for over a decade, produced only guttural sounds when rescued. Four years later, she could produce some short sentences. Despite intense tutoring, she never did develop adult forms of grammar and would say, “M. say not lift my leg in dentist chair” (Reich, 1986, p. 302). However, a possible genetically programmed “critical period” for learning grammar

rules plus severe deprivation of human loving interactions plus poverty of any early intellectual stimulation may all have been responsible for her speech lacks. According to Catherine Tamis-LeMonda and colleagues, research does confirm that when parents encourage and expand children’s vocabulary and linguistic knowledge, then children typically show more rapid growth in language.

Language Domains

Different theorists focus on explanations for development in five major language domains: phonology, morphology, syntax, semantics, and pragmatics.

Phonology

Children need to learn to pronounce the sounds (*phonemes*) of the language of their culture. Sound production advances in fairly lawful ways in English. Open throaty vowels and coos appear early. Labial consonants are easiest and result in early combinations such as “mama” or “dada” that parents hear with delight. The most difficult consonant for many children to pronounce is *r*; hence, a toddler may exclaim “wab-bit” on seeing a bunny. Some consonant strings remain difficult for preschoolers, such as *str* in “street.” Articulatory deficits in sound pronunciation are sometimes caused by physiological abnormalities or difficulties in coordination of tongue, palate, larynx, and lips.

“Parentese” has been proposed as a way to encourage infant sound production. During intimate turn-taking-talk with baby, an adult pitches the voice higher, draws out vowels, and uses short phrases and delighted tonal expression. Then an infant is more likely to vocalize sounds in response. In comparison to ordinary talk, parentese elicits cascades of neural firing from infant brains.

Children also must learn *variations* in sound pronunciation. The initial consonant *t* in “two” is aspirated more strongly than the *t* in “stew.” Differences in tongue placement and degree of aspiration account for such phoneme pronunciation differences. Experimental techniques such as

non-nutritive sucking, baby head turning, and sound spectrograms permit researchers to find out when infants differentiate sounds and when children can hear and produce voiced versus unvoiced consonants (*b* vs. *p*, for example). These techniques permit clear pinpointing of differences in infant perceptual boundaries for sounds that adults in that culture may no longer be able to distinguish or pronounce (*l* and *r* in Japanese, for example). This early infant skill has led some theorists, such as Noam Chomsky, to postulate an innate language acquisition system or device (LAS or LAD), rather than emphasize acculturation.

Morphology

Children become aware of, and learn how to use appropriately, those parts of speech that can entirely change a word's meaning. For example, adding "un" to "fair" produces "unfair," or adding "re" to "deliver" means that a package has to be brought back again to a home. Adults often model words with easy morphemes; older children need to learn more sophisticated morphemes such as "circum" in "circumnavigation." From their caregivers, toddlers often easily pick up some polar opposites (big vs. little; cold vs. hot); preschoolers still struggle with sophisticated polar opposites such as shallow versus deep.

The theory of *overregularization* is used to explain errors when, for example, a preschooler proudly declares that his mom is the best "cooker." He has learned the rule for adding "er" to define an agent (teacher, baker), but does not yet know that some agents such as "cook" do not require any special ending. Brown's research on language acquisition by Adam, Eve, and Sarah noted that these children acquired 14 grammatical morphemes in an order predicted by the rule of linguistic complexity. The present progressive ("swimming") appeared earliest. The contractible auxiliary morpheme (e.g., "Baby's going nighty-night") was the last to be acquired. Jean Berko's Wug test provides a splendid way to elicit children's understanding of English regular and irregular forms ("This is a wug; now there is another one. . . . There are two ____"). Regular endings, such

as the plural "wugs" or "baker" or "ended" follow a rule of how to apply endings for plural or agent or past tense. For irregular words ("mice"; "fell") a child must instead retrieve that special lexical item stored in memory. Thus, a young child is more likely to complain "Mommy, I fallded down!"

How do children learn words? Mandy Maguire and colleagues proposed the "SICI continuum." They theorize that regardless of a word's grammatical form, children's earliest words refer to concepts distinguished by a reliable and consistent shape, easy to tell apart from others ("individability"), perceptual salience and "concreteness," and these easily allow a child to create a mental image ("imaginability"). Their theory would predict how much more difficult words like "truthfulness" or "resilience" would be for a young child to understand compared with words such as "doggie," "up," "shoe," or "bye-bye." This theory would also explain children's use of *semantic transparency* when they construct terms such as "pig house" when they do not know "pig sty."

Syntax

Grammar rules for sentence word order differ among languages. "The white house" in English translates as "La casa blanca" in Spanish. Some languages, such as Italian or Spanish, do not always require a subject. "Es la madre" means "She is the mother" in Spanish, whereas "She" is required as the sentence subject for correct syntax in English.

Noun word endings have declensions in some languages, such as Latin and Russian, so that word order is not so important for the speaker/reader to understand what is said or written when he or she knows the declensions well. Thus, "babushkoo rebyonok bayitsa" means "The child is afraid of grandma" even though the word for grandma initiates the phrase, because that word has an accusative ending that clues a Russian-speaking child that grandma is the *object* of the child's fear and is not the subject of the phrase. An English-speaking child usually assumes that when a word is in first place in a phrase, then that word is the subject or agent. Indeed, researchers working with English-speaking children note

that decoding passive sentences is very difficult for children until they are about 4 or 5 years old. Asked to act out with soft toy animals “The puppy was hugged by the bunny” or “The puppy hugged the bunny” young preschoolers in both instances will have puppy hug the bunny.

Theorists differ markedly in explanations of how children learn to combine vocabulary words into sentences, and even embedded phrases, according to the grammatical rules accepted by their particular language group. In *Syntax Structures*, Chomsky’s rationalist formulations focused on syntax. In contrast to the empiricist Skinner, Chomsky emphasized competence rather than performance. He posited the existence of a universal grammar applicable to all utterances a language permits. He theorized that since children in all cultures learn the grammar rules of their language, and also since there are brain areas for receptive language (Wernicke’s area) and for language production (Broca’s area), then language acquisition rules must be innate. Rules for syntax learning include the concept of a core, a deep structure that signifies the relation between a subject and an object as in “Sara dresses the doll.” This core follows phrase structure rules (or tree diagrams) that divide a sentence into a noun (or noun phrase), a verb, and then an object or further embedded phrase as in “Sara was dressing the doll that had been a gift from her aunt.” Chomsky posited *transformational grammar rules* that further allow a speaker flexibly to convert deep structure (d) into a myriad of “surface structures” (s) such as imperatives (“Sara, dress the doll!”) or questions (“Sara, have you dressed the doll?”) and other forms, such as subjunctives in past or future (“Sara might have dressed the doll”), or negatives (“Sara will not dress the doll”), or conjectures (“Will Sara have dressed the doll before her aunt visits?”). Chomsky posited *transport rules* whereby a child learns to move an auxiliary verb to the front in order to compose a question (“Did Sara dress the doll?”).

Chomsky’s theoretical approach later, in *Rules and Representations*, became known as government and binding theory. This theory ties together phonetic and logical forms and phrase structure rules, lexical (vocabulary) categories, such as verbs

and nouns, as well as “complimentizer” phrases used to embed a clause within another clause (as in “This is the house that Jack built”), according to Jean Berko Gleason and Nan Bernstein Ratner. Despite Chomsky’s emphasis on the innateness of language learning, researchers confirm that when adults do recast older children’s grammar errors, then children are three to eight times more likely to try to use the corrected form with those adults, according to Matthew Saxton. Roberta Michnick Golinkoff and Kathy Hirsch-Pasek (1999) reported that “babies whose mothers routinely name objects for them have enhanced vocabularies a few months later” (p. 72). Caregivers do influence word learning.

The derivational theory of complexity (DTC) postulated that a syntactic construction that required more rules or more complex rules would be produced in language learning only after phrases requiring simpler and fewer rules. Thus, a toddler might say, “No me want soup” before learning to transport a negative word into a phrase, add an auxiliary plus a past tense lexical item, in order to say, “I did not want soup.” Discussing DTC, Reich (1986) points out that “later grammars within the transformational tradition, and grammars from other schools of linguistics, such as [Halliday’s] systemic theory [Lockwood’s] stratificational grammar or [Pike’s] tagmemic theory might well make other predictions as to complexity” (p. 310).

Katherine Nelson’s functional core hypothesis focused on concepts, instances, and attributes—the internal categories that children have, for example, about a ball: how it feels, rolls, bounces, and is thrown. Such perceptual features and experiences flesh out a child’s concept. Thus, learning the word “ball” involves associating the sound sequence for the word with all the properties, concepts, and activities already acquired.

Semantics

To succeed in school, children must decipher meaning in sentences or paragraphs. A child who decodes and pronounces each vocabulary word aloud while reading an essay may still not understand the implications of a passage. One teenager,

taking a test, read a paragraph about insect-ridden meat and was supposed to check which of four listed organizations would be the appropriate agency to supervise this situation. She checked “Civil Rights Act.” She had read all the vocabulary words, but still did not realize the meaning inherent in the paragraph’s description of tainted food that could definitely harm human consumers, so responsibility for food safety would come under a Consumer Agency, a choice the test clearly did provide.

Theorists need to grapple with the fact that familiarity with accepted grammar usage may be quite separate from semantic ability. Indeed when a toddler at a birthday party saw a peer bite and deflate another child’s balloon she urgently called out, “Baby other balloon bite—NO!” Her mom understood the semantics very well. Her toddler did not want that peer to bite and deflate her balloon too. Sophisticated semantic decoding abilities may well be linked with cognitive abilities as well as language learning opportunities. Full semantic sophistication includes understanding puns, sarcastic put-downs couched in seemingly innocent phrases, and which words are “cool” to use with peers. Children need to learn the subtle semantics of *indirect speech*. A parent exclaiming “This living room is a mess!” impels some youngsters hurriedly to clean up toys while other children might keep on playing without understanding the implicit request in that parental exclamation.

What accounts for increasing sophistication in learning semantics? After careful longitudinal observations of mothers interacting with babies as they gradually acquired words, Jerome Bruner (1983) set forth an intriguing theoretical proposition: “Language acquisition appears to be a by-product (and a vehicle) of culture transmission. Children learn to use a language initially to get what they want, to play games, to stay connected with those on whom they are dependent. . . . The engine that drives the enterprise is not language acquisition per se, but the needs to get on with the demands of the culture” (p. 103). Bruner asserts that “language acquisition is continuous with and dependent on the child’s acquisition of his culture [consisting] of symbols, procedures, concepts and

distinctions that can only be made in language. Language, in consequence, cannot be understood save in its cultural setting” (p. 134).

Pragmatics

Children need to learn the ways in which adults in their culture consider it appropriate or polite to speak to peers, parents, elders, bosses, or teachers. Words as well as expressions differ in cultures where children must learn modes of speech appropriate for different persons and social positions. In France, one uses the familiar “tu” to peers and family members, but “vous” more formally with teachers and adults. In English, youngsters learn that grandparents are shocked at hearing “poopy-head,” whereas the child cheerfully uses this term while bantering with a peer.

Bilingualism

Knowing how to speak and read more than one language is an urgent requirement in today’s global economy. Parents in Hong Kong and other nations strongly support and promote young children’s learning English (Honig & Lim, 2016). Yet theorists used to claim that learning more than one language in the early years would decrease children’s cognitive and language abilities. In contrast, recent research shows that bilingual children show enhanced cognitive flexibility and ability to focus attention with “more complex representational structure that includes two languages” (Bialystok, 2015, p. 120). Theories of how best to teach bilingual children have ranged from vocabulary drill (which does not lead to conversational fluency) to creative ways for children to learn phrases while interacting, for example, in a ball-tossing game. Teachers need sophisticated attunement to the kinds of errors in pronunciation, grammar, and writing that a first language may pose for a child.

Emergent Literacy

Researchers and educators focus more and more on emergent literacy. The components include

children's ability to listen, comprehend, and use oral language; awareness of words as separate from pictures; knowledge about letters in words; recognition of phrases and sentences; and phoneme/grapheme correspondence. These requirements can lead to frustration for children who struggle with dyslexia (spelling and reading difficulties). Children also need to learn when there are exceptions to correspondence rules. For example, *o* in "rote" is pronounced the same as *o* in "moat," although the orthography differs for those two words. Two learning processes have been theoretically posited by Grover J. Whitehurst and Christopher J. Lonigan as *outside-in* and *inside-out*. In the outside-in process, children come to understand that the "squiggles" on a page are print. They learn that there are conventions as to the way to read the squiggles and that the words have meaning and orderly progressions. They learn vocabulary and how narratives are constructed in sequences of words. In the inside-out process, constructs of emergent literacy include knowledge of letter names, letter-sound knowledge, and awareness of grammar. For tiny children, early literacy development is interdependent with and interwoven with early oral language development (Honig, 2008).

During interactive storybook reading, children learn the difference between the beginning and the end of a book, how to turn pages, and the direction of reading print on a page—from left to right and from top to bottom of a page (for English). When parents frequently and generously share early joint book-reading experiences, meta-analyses confirm that young children acquire superior proficiency learning to read, according to Adriana G. Bus and colleagues.

What variables have been implicated in worrisome delays in emergent language and literacy skills? Poverty, family dysfunction, child abuse/neglect, parental mental/physical illnesses, and very premature birth are some of the more sobering causes of children's struggles with reading and language mastery. A great sorrow for children with aphasia (language deficits due to brain impairments) or autistic difficulties is the lack of ability to use language for positive social

communication with others, according to John Harris. Structural variables, such as parental age, child gender/birth order, number/spacing of siblings, and number of children's books in the home, may affect early language learning. Process variables, such as language-related experiences, including language use at home, and early educational experiences affect language learning. The infant who is "shushed" rather than encouraged to vocalize in a child care setting loses a precious opportunity for glorying in his or her nascent language abilities. Teaching sign language to preverbal infants eases frustration. Making the sign for "more" empowers a preverbal infant to request manually more Cheerios cereal. Deaf children in an orphanage in Nicaragua created their own manual sign language. This suggests that there is an innate mechanism impelling social creation and use of language.

Conclusion

No one theory addresses all the mysteries of how very young children develop sophisticated skills in speaking, writing, and reading. Any widely encompassing theory will have to take into account many different contributors including genetic hard wiring and a possible critical period for some aspects of learning syntax; culture; beliefs and practices; breadth of experiences offered to small children such as play outdoors; daily dialogic picture book-sharing; meal-time rich conversations; visits to cultural events/centers such as museums, zoos, exhibitions, fairs, and nature reserves; quality of emotional relationship with caregiver; intactness of articulators and of brain and neural circuitry; child cognition; and peer pressure. A comprehensive theory of language development thus will require the combined efforts of many different professions in order to explain the great variability, complexity, and uniqueness in child language learning powers and usages.

LANGUAGE DISABILITIES

Language is a complex, rule-based system that humans use to express their wants, needs, thoughts, and emotions as well as to understand the wants, needs, thoughts, and emotions of others. Children with language disabilities struggle with existing language rules and as a consequence, struggle with making themselves understood and understanding others around them. For children entering formal schooling, the presence of a language disability can have significant negative effects on their ability to participate and benefit from classroom instruction, even as early as preschool. This entry explores what it means to have a language disability and considers the impact of language disabilities on children's educational experiences.

Defining Language Disability

A hypothetical scenario illustrates how language disabilities may affect students' speech and comprehension. Jasmine is a 4-year-old child who

started preschool in the fall. Jasmine's teacher, Mr. Edwards, noticed that she was having a hard time settling into the routine of the class. He can understand the words she says, but he finds it difficult to follow what Jasmine is talking about. For instance, during circle time Jasmine might share, "I goed to that place I hadn't go to before." In addition, Mr. Edwards noticed that her sentences often sound simpler than those of her peers, contain lots of grammatical errors (e.g., "goed" for "went"), and she frequently mixes up pronouns, using "he" for girls and "me" instead of "I" (e.g., Me wants more juice). Besides the talking, Mr. Edwards has learned that he has to explain center activities to Jasmine several times, and that she is only able to listen to one instruction at a time. If he asks her to do two or more things (e.g., *Take off your coat* and *put it in your cubby*), she will forget what she was asked to do.

Jasmine, like so many children with language disabilities, presents with difficulties across a range of language areas. The rules of language are best understood in three main areas: content, form, and use. The remainder of this section discusses each area of language and how each might impact education.

Content

The content of language is the meaning behind what is said. Children with age-appropriate content have a wide variety of vocabulary words, understand new words with ease, and use the right words in the right context. In contrast, children with language disabilities demonstrate a significantly reduced range of vocabulary words. They have fewer words at their disposal, and often rely on "filler" words such as "thing," "stuff," and "it" instead of using more precise terminology. This reduction in content not only makes it hard for children with language disabilities to adequately express themselves, but it also makes it difficult for them to understand what others are saying to them.

Children who struggle with the content of language may find it difficult to learn new vocabulary words and academic concepts in class. Children

with language disabilities often need to hear new words and concepts multiple times, with explicit instruction, exemplars, and visual supports, to learn and retain that new information. Typically developing peers, on the other hand, learn new words and concepts with significantly fewer presentations. Children with language disabilities in the area of content may find it challenging to understand the vocabulary words used by teachers and peers, which often leads adults and peers to conclude that the child with language disabilities is "not listening."

Form

The form of language is the structure and organization of the sounds, words, and phrases used to communicate. Another way to think about form is the grammatical rules and conventions that dictate how we put words together to form coherent thoughts. Children with language disabilities may exhibit several grammatical errors, such as dropping word endings (e.g., "I have three *book*" instead of "*books*"), omitting functor words and auxiliary verbs (e.g., the, a, an, is, are), using incorrect verb tense (e.g., "I goed to the store" instead of "I *went* to the store" or "He *run* fast" instead of "He *runs* fast"), and improper use of pronouns (e.g., confusing "he" and "she" or "me" and "I"). Children with language disabilities are often described as sounding "immature" due to use of simple sentence structure (subject-verb-object) without any elaboration, such as noun phrases or verb phrases, or complex sentence structures.

Deficits in the area of language form not only make it difficult for a child to adequately express his or her thoughts, but can cause miscommunication for children with limited understanding of grammatical structures. Understanding verb tense, for example, impacts a child's comprehension of a story as well as the ability to follow directions in class. Children with language disabilities, in an attempt to understand directions, may perform actions in the order of mention rather than the order intended. For example, a teacher who instructs, "Before you go to centers, write your

name on your paper” clearly wants the children to write first and go to centers after. But a child with language disabilities, who doesn’t understand the complex form of this sentence, will likely go to centers first, because that direction came first in the directions.

Use

Use refers to the way children access and apply language in context, or said differently, refers to the functional application of the content and form of language. Children with language disabilities who struggle with the use of language may experience a restriction in the reasons they use language. They may be able to use their language to ask for things that they want, say hello to friends, and protest an action they don’t like, but struggle to answer questions appropriately, ask questions, or engage in conversation. Children with language disabilities will often have difficulty staying on one topic of conversation, will assume the listener knows more information on the topic than they do, and may tell stories in a disorganized fashion, making it difficult for listeners to understand. Additionally, children with language disabilities may exhibit awkward social interactions with peers and adults, including avoiding eye gaze, standing too close to conversation partners, struggling to enter into play routines with peers, and forgetting the rules of the classroom, such as raising their hand to speak.

Difficulties in the use of language put children with language disabilities at a disadvantage in the classroom. They struggle to make and maintain friendships and often lack a close bond to the teacher. Children with language disabilities may also struggle to answer questions in class or participate in class discussions in a way that others can understand. As a result, many teachers find it difficult to accurately assess what the child with language disabilities does and does not truly understand. Furthermore, children with language disabilities will often not ask for help or indicate that a word or concept was unclear, resulting in increased need for comprehension checking by the educator.

Educational Risks Associated With Language Disabilities

Language disabilities impact a child’s ability to communicate with adults and peers in his or her environment, but also have significant effects on a child’s early educational experiences. Children with language disabilities are at increased risk for weak emergent literacy skills, poor school readiness, fewer positive relationships with teachers and peers, and long-term academic failure.

Emergent Literacy Skills

Language is important not only to communication but also for academic mastery, specifically in the area of emergent literacy. Emergent literacy refers to the preliterate concepts a child must master to be able to transition to true reading. Emergent literacy includes concepts such as letter–sound awareness, phonological awareness, and print awareness. Children who are diagnosed with language disabilities often demonstrate difficulties with emergent literacy skills as well. Specifically, a child’s breadth and depth of vocabulary knowledge as well as understanding of the grammatical rules of language lay a strong foundation for using language in a literate context. Children without such a foundation will struggle to acquire emergent literacy skills, placing them at significant risk for delays in reading decoding and reading comprehension.

School Readiness

School readiness refers to the learning-related skills or behaviors children need to be able to successfully navigate the educational arena. School readiness behaviors include skills such as following directions, remembering the rules of the classroom, working independently, and cooperative play in groups. Children who enter preschool and elementary grades with strong school readiness skills make more gains academically, and at a faster rate, than children with weak school readiness behaviors. They are able to focus on the academic instruction, and benefit from teacher help more so than their peers with weak school readiness

behaviors. Children with language disabilities are understood to exhibit weak school readiness behaviors, on average, which puts them at further disadvantage academically.

Relationships With Teachers and Peers

As already discussed, children with language disabilities often show delays in the “use” of language, or the social skills surrounding language. As a result, children with language disabilities generally have fewer friends in class, struggle to connect with their teacher, and are at an increased risk of bullying. This is significant, as studies have suggested not only that positive relationships in the classroom create a safe place to learn and take risks, but that children who feel safe and welcomed in class make more progress over time than children who feel vulnerable. The closer a child feels to his or her teacher, the easier it is to request help, learn and apply new information, and participate in challenging activities. Children who do not feel as close to their teachers may not be as willing to be vulnerable in class, which may have negative effects on the amount of academic growth they experience.

Long-Term Academic Delays

Furthermore, research suggests that children who begin school with language disabilities are not only at risk for delays upon entering school, but are at risk for persisting academic delays through elementary school, into adolescence, and even into adulthood. Children who struggle with basic communication skills across the three areas of language (content, form, and use) fall behind their typically developing peers in early childhood. Once they fall behind, it is very difficult for children with language disabilities to “catch up.” Even with intervention, children with language disabilities may be able to remedy their conversational skills, but continue to struggle with the academic aspect of their language, including reading, reading comprehension, and more abstract thought processes required for science and applied math.

Conclusion

Children with language disabilities present with difficulties across three main areas of language, including content, form, and use. Young children experiencing difficulties in these areas of language not only struggle to communicate basic ideas to others and comprehend what others say to them, but they also struggle academically. Language permeates every facet of our world and for children with language disabilities, language *problems* permeate all aspects of their world, including early childhood education. The more educators can understand the role of language in communication skills and academic progress, the better position they are in to support learning for children with language disabilities. It is critical that early childhood educators work collaboratively with speech-language pathologists to ensure that children with language disabilities fully benefit from their educational experiences in the classroom.

LANGUAGE DIVERSITY

Language is a system of linguistic features, such as sounds (phonology), meaning (semantics), grammar (syntax and morphology), and social aspects (pragmatics). These features form a system of words and sentences that people use to express their thoughts and feelings. More than 6,500 languages are spoken in the world today. In the United States, English is the most common language, followed by Spanish. Many children in today's schools are dual language learners, or children who are learning both their native language and a second language. This article addresses the variations within a language, such as nonstandard dialects, terminology, demographics of nonnative language learners, and teaching models and approaches used by schools. With the increase of young dual language learners in early childhood programs and classrooms, it is important that educators and caregivers understand and support the diversity in language development of children.

Variations and Nonstandard Dialects

Standard English is the form of English that has been determined to be acceptable as the national norm by the majority of the educated population in the United States. Standard English evolved based upon the spoken and written language of the majority Caucasian population who historically had the most power, wealth, and political influence in the country. It is not necessarily a superior form of English in terms of having the most logical rules or syntactical complexity, but is considered appropriate for formal or business settings. There are, however, variations in dialect and accent. Dialect refers to variations in words, grammar, and pronunciations in a language spoken by a sizable group of people, which may be related to a geographical region, race, gender, age, or social class.

One variation of nonstandard dialect is African American English (AAE) (also called Black English or Ebonics). While the name implies that this dialect is a racial dialect, it is actually a sociocultural dialect, often spoken in many sections in the southern

United States by low socioeconomic speakers, regardless of race. The AAE dialect has its origins in Africa and slavery in the South, with the dialect spreading to racially segregated urban areas. Examples of this dialect include final consonant deletions, such as “most/mos,” unstressed syllable deletion, such as “government/gov’mment,” and consonant reversals: “ask/aks.” In addition to these phonological variations, AAE has syntactical rules, such as plural -s not being required if the sentence indicates a plural amount: “She has five dollars/She got five dollar” and the use of triple negatives to emphasize the negations: “She doesn’t have any money/She ain’t got no money.” AAE also includes the syntactical use of the word “be” to indicate a continuing state, with the absence of “be” indicating a temporary state. For example, “She be talkin’” refers to someone who talks a lot, while “She talkin’” refers to someone who is presently speaking. Young children who are raised in homes and communities with the predominant use of AAE bring the dialect to the classroom in both their speaking and writing. However, with exposure to Standard English, they learn when to “code switch,” or use the dialect that is appropriate for the social setting. By the upper elementary grades, the majority of AAE speakers begins to understand the social significance of dialects and can readily converse in either dialect, depending upon the formality of the setting.

Another socially acceptable example of a variation in dialect in different areas of the country is the use of the word “you” changing to “you guys,” “youse guys,” “y’all,” and “you’ins.” Accents are variations in pronunciation, usually in relation to a particular region or country. For example, individuals from Boston may say “pahk da cah” instead of “park the car,” as the Boston accent deletes the “r” sound.

Dual Language Learners: Terminology

Dual language learners (DLLs), also called English language learners (ELLs), refers to children who are learning a second language, while often still learning their home or native language. As children become bilingual, or proficient in both languages, their primary or dominant language may or may

not be their native language. In some cases, as the second language is acquired, a child may lose his ability to speak in the native language. This is known as *subtractive bilingualism*. Children receiving instruction in both languages may also become biliterate, where they are also able to read and write fluently in both languages. In a school setting, children who are learning English as their second language may be labeled as limited English proficient (LEP) because they are not able to speak English fluently. These children need support of some type, such as an English as a second language (ESL) program. Once a child is able to speak English as well as a native speaker, he or she is considered to have fluent English proficiency (FEP); however, the student may still need support in acquiring formal academic oral or written language skills. Research shows that dual language learners generally become socially competent in basic conversation skills, or basic interpersonal communicative skills (BICS), in a second language within 2 years, while the ability to use language in a formal, academic manner, cognitive academic language proficiency (CALP), may take 5 to 7 years to develop fully.

Dual Language Learners: Demographics

Due to a history of immigration, the United States has always had a variety of languages spoken by its inhabitants. The U.S. Department of Health and Human Services reported that this diversity began to wane in the early 1900s with more restrictive immigration policies, a major depression, and world wars that caused the number of English language learners to dwindle to 4.7% by 1970. However, immigration numbers began to increase in the 1970s, bringing an increase in non-English-speaking residents to 20.3% by 2010. Census data from 2011 reported Spanish as the most common language spoken other than English, with a dramatic increase of 210% since 1980. The National Clearinghouse for English Language Acquisition reported that in 2011 the five home languages most frequently spoken by English language learners in the United States were Spanish, Chinese (Cantonese), Vietnamese, Arabic, and Hmong.

The Census Bureau's 2011 American Community Survey asked speakers of other languages to self-identify their ability to speak English on the following scale: very well, well, not well, or not at all. Almost 26% of Spanish speakers, 30% of Chinese speakers, and 33% of Vietnamese-speaking people reported they did not speak English well or did not speak English at all. These statistics illustrate that children who are not fluent in English are likely to have adults in the home who struggle with English.

Today, in U.S. public schools, language diversity is seen in all areas of the country. In 2012–2013, 9.2% of public school students, or 4.4 million students, were ELLs, according to the National Center for Education Statistics (NCES). The percentage of public school students who are ELLs ranges from over 10% to less than .7% depending on the state. Larger percentages of ELL students were seen in urban school districts, with ELL students making up 16.7% of students in large cities and 3.5% in rural areas in 2012–2013, according to NCES.

Language diversity is prevalent in Head Start programs, with almost three in 10 children in Head Start coming from families whose primary language is not English. The Office of Head Start reported in 2008 that only 16% of all Head Start programs serve only children whose primary language is English. This trend of growth in English language learners in early childhood and public school programs is expected to continue. The U.S. Census Bureau projects that due to immigration and birth rates in non-English-speaking families, children whose home language is other than English will increase from 22% to 40% of the school-age population by the 2030s.

School Models and Programs for Dual Language Learners

There are varieties of approaches used with dual language learners:

Additive Bilingualism. Learning a second language is promoted while students continue to learn the first language. Research shows that there are

cognitive benefits for a child who maintains the first language while learning a second language.

English as a Second Language Program. In an ESL pull-out program, ESL students meet with the ESL teacher outside of the regular classroom for a short period each day or week to receive intensive help in language acquisition.

Native Language Instruction. All instruction is provided in the students' native languages with the goal of mastery.

Submersion. Nonnative-English-speaking students are placed in English-speaking classrooms. The goals of this model are to have the student learn English and assimilate to North American society. The first language is not supported and is frequently lost in this subtractive model.

Dual Immersion. This method, also known as two-way immersion, bilingual immersion, dual language immersion, two-way bilingual immersion, or developmental bilingual education, provides integrated language and academic instruction for nonnative English speakers and native English speakers. This approach can lead to bilingualism for both ELLs and native-English-speaking students.

Sheltered Instruction. A modified curriculum is provided that integrates content area objectives and language development objectives. This approach makes academic instruction more accessible to students at different levels of English proficiency. A related program type is the sheltered model, where ESL and content area classes are combined and are taught either by an ESL-trained subject area teacher or by a team.

Transitional Bilingual Education. The native language is used to support content area learning, while the student learns English. In this method, learners are enrolled in content classes, which are taught in their native languages, while also taking English as a second language classes. These students may take other classes taught in English that require less language proficiency. Although students move from their native languages to English,

the goal is assimilation and the outcome is generally subtractive bilingualism.

Maintenance Bilingual Education. With the goal of promoting bilingualism and biliteracy, first language support is provided while learners are transitioned into English content classes. Students receive language arts instruction and content area instruction in their native language during this transition.

Enrichment Bilingual Education. Instruction for both native and nonnative English speakers in content classes is provided to achieve the goal of all students developing biliterate and bilingual skills.

Language Preservation/Revitalization Programs. This model is found on several Native American reservations where children speak English, but do not speak their Native American tongue, such as Wampanoag or Cherokee. Early childhood programs on Native American reservations, such as Head Start, offer instruction in the Native American tongue, helping children become bilingual in both English and the language of their heritage and halting the extinction of the language.

Supporting Language Diversity

It is important that early childhood educators and caregivers value the native language of a child. Research has shown that supporting children in learning their home language leads to greater success in learning English. Because language and culture are intertwined, this support shows respect for the child's family and culture, which can foster a sense of self-worth in a child. Fluency in the home language strengthens family bonds, allowing children to communicate with parents, grandparents, and other family members who are non-English-speaking. Finally, supporting linguistic diversity in the classroom can enhance the social skills of all children, as they experience mutual acceptance and respect.

LEADERSHIP IN EARLY CHILDHOOD EDUCATION

The contribution of effective leadership to organizational development and change, and to the

raising of achievement in different educational contexts, is widely accepted. While there has been a growing interest in early childhood education (ECE) leadership from multiple countries, including New Zealand, England, the United States, and Australia, research in this sector has been more limited and dominated by a small number of researchers. In this context, Daniel Muijs and colleagues noted that ECE leadership has not been strongly theorized or related to school leadership literature. Much of the existing literature has focused on the roles and characteristics of ECE leaders, and there has been a need to identify what effective leadership practice is in terms of processes and outcomes. There was also a lack of leadership training, leaving some new leaders reluctant to take on the role and for those who did so a feeling of being underprepared.

Due to the complexity of the nature of leadership, existing literature points to the absence of a universal definition of leadership in early childhood education. At a time of rapid policy change, however, there has been an increasing emphasis on multidisciplinary teamwork and a new style of shared or distributed leadership with the capacity to improve outcomes for young children and families, especially those most vulnerable. With the understanding that a common definition of leadership in early childhood is evolving, this entry provides current information on what the field sees as essential to an understanding of effective leadership.

Since the 1990s, with strong policy and public attention to ECE, many Organisation for Economic Co-operation and Development (OECD) countries have focused on expanding access, improving quality, and developing more coherent and coordinated policies. The 34 member countries of OECD, which include the United States, have followed different models for organizing ECE systems, with potential implications for quality regulations and staffing, including a focus on leadership. A small but increasing number of countries have developed integrated care and administrative arrangements under the auspices of departments of education, resulting in more centralized and prescriptive approaches to decision

making, regulation, monitoring, and evaluation of learning and achievement. A contextual analysis of ECE leadership by Eeva Hujala, based on Urie Bronfenbrenner's bioecological theory, drew attention to all these operating environments of leadership, from the micro level, closest to the leader to the institutional structures and macro-level societal values that define leadership. Jillian Rodd has remarked upon a shift to systems leadership where ECE leaders focus on building leadership capacity within their own setting while working with and supporting other provision in the local area settings to enhance quality across the sector.

Leadership is globally seen as socially constructed, situational, and interpretive. Peter Gronn and Peter Ribbins established a link between human agency and social structure as a central question in contextual leadership research, distinguishing between studies that "psychologised" leadership and focused on role, and other studies that focused on the relationship between task structure, system, and environmental complexity. Manjula Waniganayake has advised taking account of the person (leader), the position (authority to make decisions), and place (organizational setting) in research on ECE leadership. Tony Bush (2014, p. 543) identified many models of educational leadership, distributed leadership being "most favoured" among educational leadership scholars. Distributed leadership is a democratic approach that is based on a culture that extends to full participation from school staff with change emerging from the bottom up rather than more hierarchical models where change is mandated from the top down. Bush also noted that instructional or pedagogical leadership was regaining significance. Anne Marie Coughlin and Lorrie Baird noted that the primary focus of pedagogical leadership is to build a culture of reflective practice by supporting early educators in their quest to make their teaching better by encouraging curiosity and openness so that practitioners learn from their own teaching. In this respect, Johanna Heikka and Waniganayake have aligned distributed ECE leadership with pedagogical leadership enactment in early childhood settings. Distributed ECE leadership assisted in the understanding of leadership as enacted by a

dispersed set of stakeholders, while pedagogical leadership reflects the core purpose of ECE in Finland, as elsewhere.

An exploratory study in New Zealand by Cushla Scrivens identified a desired leadership style emphasizing consultation, communication, and empowerment that did not sit easily with an increasingly neoliberal climate of competitiveness and control. Christine Woodrow and Gillian Busch (2008, p. 83) noted that ECE practitioners in Australia did not readily identify with leadership in a situation of "increasing control of the profession through mandated curriculum and auditing and the rise of corporate childcare and commodified children's services."

A system of centralized control has been found by researchers in Asia as well. In a 2014 study, Chi Wai Chan explored principals' leadership styles in Hong Kong, noting that they were expected to be autocratic, in line with Dora Choi Wa Ho's 2010 report of centralized approaches to ECE leadership. Chan's finding that kindergarten teachers perceived their principals as collaborative and participative was attributed to kindergartens' small size and simpler organizational structures. Cheng Yong Tan and Clive Dimmock (2014, p. 1) found that more direct government control in Singapore was being replaced by "a more subtle centre-periphery relationship." Marjory Ebbeck and colleagues, however, found that some Singaporean preschool teachers have reported cultures where principals and senior teachers were not willing to share status as a factor in their reluctance to take on leadership roles.

While central to effective ECE leadership is raising ECE attainment, this area remains unexamined by the majority. In order to identify the contribution of leadership to early childhood settings identified as effective by the Effective Provision of Pre-school Education (EPPE) project, Iram Siraj-Blatchford and Laura Manni drew on demographic information, policies, documents, observations, and interviews with managers to link leadership behaviors to the improvement of children's learning outcomes. Fundamental requirements for leadership for learning in this study included an ability to perceive contextual literacy

(seeing how context is shaped by multiple conditions in early education settings), a commitment to collaboration, and dedication to the improvement of children's learning outcomes.

English Sure Start children's centers, launched to offer disadvantaged children and families integrated services, including child care and early education, health, and social welfare services, provided a distinctive multi-agency model of ECE leadership. An evaluation by Caroline Sharp and colleagues of the National Professional Qualification in Integrated Centre Leadership (NCSL) identified clusters of centers working together on strategic goals; a cluster model with a locality manager responsible to the local authority; a hub-and-spoke model, where the hub center leader was responsible for work of satellite or "spoke" centers—as well as centers subsumed within other organizations and agencies. Leaders' self-report of program impact included personal impact on themselves and attitudes toward their own roles, changes in leadership behaviors and strategies, improvements in collaborative working with other agencies, and center-staff teams working as "learning communities" that were likely to impact children and families.

Lack of leadership development programs is an unresolved issue. Studies of program effectiveness have led to professional learning and leader capacity building, where leaders are encouraged to develop themselves and their staff teams through coaching and mentoring, and ultimately to engage children and families. More recently, Teri Talan, Paula Bloom, and Robyn Kelton have evaluated a leadership development model that emphasized individual leader characteristics, systems change, and program director roles as an agent of change. Specific training geared to individual director needs along with strong mentoring was found to lead to firm advocacy roles for directors. Directors who see themselves as advocates and engage in advocating for the early childhood profession are more likely to serve as leaders than directors without specific administrative training.

In regard to early childhood programs that are housed within PreK–12 school systems, elementary school principals are most often charged with overseeing teachers assigned to grade levels that

include PreK–3, but also may include Grades 4 and 5. Multiple studies have found that principal certification in nearly all states of the United States does not typically require coursework or praxis that focuses on child development, developmentally appropriate practice, systems theory, or the importance of family engagement—all underpinnings of effective early childhood education. The Center on Enhancing Early Learning Outcomes (CEELO) points out that principal leadership has an impact on child outcomes that is second only to effects of teaching. As principals serve as leaders of basic education structures that include PreK–3rd grade and are charged with evaluation of teachers who have been prepared to teach young children, greater opportunities for professional development are needed to increase understanding of transitions made by children and families as children move from birth–5 programs to PreK–3rd grade. In the meantime, models of distributed leadership appear to have potential in that principals and teachers may work more collaboratively and learn from each other.

Globally, policy makers are increasingly aware of the importance of early childhood education, particularly for children from low-income households, and effective leadership is now recognized as central to improvement. Thus, additional research regarding the meaning of leadership in early childhood education is needed in order to identify responsible entities as accountability takes the forefront. For all educational leaders, this may be best accomplished through an identification of ways that early childhood education is a unique field of study with multiple areas of research that support application of principles such as understanding child development, young children's approaches to learning, and family engagement. Such content, along with understanding and implementing advocacy efforts, will serve as a basis for early childhood education leadership development.

LEARNING MATERIALS

Learning materials are the tangible things teachers provide to foster exploration, understanding, and mastery of concepts and skills. In early childhood, learning materials are particularly important because children's access to and interactions with materials during this period influence their developmental and academic progress. This entry focuses on how and why materials are used to promote learning with young children.

Early Childhood Materials

Young children are “concrete” thinkers; they need materials of all kinds to explore their capabilities, interests, and environment. Working with materials helps them (a) process stimuli; (b) discover and understand the physical properties of objects; (c) practice emerging physical, social, and intellectual skills and language; and (d) provide an outlet for the imagination. The spectrum of materials for young children ranges from open-ended items that can be used flexibly for many different purposes (such as play dough, paints, and writing tools) to ones designed for a specific and limited purpose (such as a matching game for identification of vowel sounds or a composition book used for recording daily journal entries).

The development of early childhood materials has been influenced over time by individuals considered pioneers in the field. The idea that materials should be specifically designed for young children as an important part of the curriculum is generally attributed to 19th-century educator Friedrich Froebel. Child-sized furniture and many toys and materials used today were inspired by Maria Montessori's work in the early 20th century. Caroline Pratt is credited as the inventor of unit blocks in 1913, a staple in early childhood classrooms for the past 100 years.

Today, materials are considered an indispensable component of early childhood curriculum. Most commercial curriculum products either include or offer accompanying materials, and teacher education textbooks typically incorporate extensive discussion about the role materials play in early learning. The materials market is supported by an extensive network of specialty vendors, but teachers also use everyday or recycled materials to help children make connections between their play, learning, and real-world lives. Online and print resources are also very helpful to teachers, providing them with recipes, examples, and “do-it-yourself” ideas for both making and using materials with children.

How Teachers Use Materials

The materials children prefer and how they learn from them varies as development progresses. Babies and toddlers enjoy interaction with objects; their curiosity focuses on physical properties and how an item can be manipulated. Preschoolers are developing social skills and are primarily interested in pretend play. Elementary-age children enjoy intellectually challenging games with rules and are beginning to think abstractly to problem solve. So, for instance, a 2-year-old would be very happy pushing a small plastic grocery cart back and forth repeatedly due to fascination with the way the wheels work, while two 4-year-olds would fill the same cart with play food for a planned imaginary grocery shopping trip. A second grader might be asked to estimate how much food the cart could hold and figure out what the

grocery bill might be if he or she was to purchase all the items.

Teachers choose materials to create opportunities for learning and development, and support observed interests and needs among their students. The curriculum in use may either directly or indirectly guide decisions about what and how materials will be used and made available to children. Typically, teachers use equipment (e.g., tables, carpets, storage units) to define and differentiate spaces for activities. Commonly designated areas in preschool classrooms include blocks, dramatic play and/or housekeeping, manipulatives, sand/water, arts, literacy, math, and science. Materials in elementary school classrooms gradually begin to focus more on print and technology resources and less on materials intended for play.

Teachers arrange materials in interest or work areas so that children can find what they need, follow directions, and put materials away when finished. They often use particular strategies to encourage independence and responsibility, such as a sign with photographs depicting steps for setting up and completing a science experiment. They think carefully about compatibility across areas as well; for instance, a book corner and writing center would be located away from noisy activities.

Teachers intentionally select materials that will support both generalized play and specific tasks/activities. Three areas considered essential for young children are blocks, literacy, and dramatic play. A block area for 3- to 6-year-olds would feature *unit blocks*, wooden shapes sized in multiples or fractions of a standard 5.5" L × 2.75" W × 1.375" H block. There would also be auxiliary blocks such as cylinders or planks and small “props” such as people, vehicles, or animals that children would use to populate constructions like a race track, farm, or airport. The teacher might post photographs of buildings or children's block constructions for inspiration and reference.

A dramatic play or housekeeping area typically contains child-sized home/kitchen furniture with props for cooking and other family life activities. As children's imaginations develop and their interest in pretend play emerges, often teachers add

items related to observed themes of interest, such as a veterinarian's office, a hair salon, or a pizza restaurant.

A literacy area would be stocked with books selected for the reading and interest levels of children, a comfortable area for reading, an MP3 or CD player with headphones for listening to or recording audio stories, a variety of writing tools, papers and writing surfaces of different kinds, and other implements children might choose for making books, posters, or other products such as a stapler, scissors, and paper hole punch.

LITERACY

What does literacy mean for young children? The most basic definition of literacy is the ability to read and write. From an early childhood perspective, literacy also must include an understanding of what comes before learning to read—how we help children gain the skills and dispositions to make literacy a fundamental part of their daily lives, as well as something in which to take pleasure.

Building early literacy skills has been identified as a central feature of high-quality early education in the United States. That being said, understanding how to balance both explicit and implicit approaches to literacy instruction is a challenge for early childhood teachers. While implicit approaches—having excellent reading materials available and accessible, labeling materials with both words and pictures, and so forth—were traditionally believed to be enough to help ground children's early literacy skills, a large body of research now points to the absolute necessity of explicit engagement with literacy. These explicit approaches require teachers to do more than prepare a literacy-rich environment—from this perspective teachers must also engage children in letter and word learning and in shared reading and discussion of texts. In addition, they must do this across a broad swath of genres (not just beautiful story books), and create linguistically and conceptually rich interactions for children in order to build both their vocabulary and conceptual understandings. While this is all true, too much explicit instruction, particularly teacher directed, can turn literacy experiences into drudgery and focus attention on basic skills alone without making room for the important conversations during shared reading that feed the engines of understanding. Similarly, we know from the research that too much reliance on implicit strategies can leave, and has left, children without key pieces of knowledge and/or understandings when it comes time to learn to read. Finding a balance and supporting teacher development and family practices toward engaging, interactive literacy experiences is imperative, particularly for young children from at-risk backgrounds.

This entry first provides a brief overview of current research about how children learn to read, then discusses what research has revealed about best practices in literacy in early childhood settings and the ways in which research highlights that these practices are and are not being taken up in early childhood settings, as well as some reasons for why or why not. This gap between research and practice, and the necessary professional development to bridge this space, is of central importance to ensuring that all young children have

every opportunity to learn to love to read. Finally, the entry discusses how to make literacy a more visible element of our daily lives and in the lives of young children by naming literacy, talking about when and why we read, and building this knowledge in young children.

Current Research About Learning to Read

Current research into early childhood literacy tells us that the period before formalized schooling is an important time for the development of the fundamental underlying skills that make reading and comprehension possible. This section begins with a broad overview of how and why we know that these skills are important. To do this, we look at what research tells us about learning to read. Learning to read is not the whole of “literacy,” but learning to read is centrally important to being able to engage in literate lives.

Research tells us that struggling with reading in kindergarten is highly predictive of poor reading skills in fourth grade. Given this, a central focus in early childhood practice needs to be “setting the table” for learning to read. This means giving children a set of tools to help them engage with reading in an almost seamless manner when they reach the age of formalized schooling (usually kindergarten). To know what tools children need, we need to know existing findings from research.

Extensive research has shown us that there are two main elements of learning to read that support future reading skills: decoding and comprehension. Decoding (the ability to break apart sounds and/or recognize sight words in order to read them) and comprehension (the ability to understand what the words mean) are two skills that both support one another and have unique importance. These two skills work together to make a child a successful reader. However, it is not a given that a child who is successful at one skill will also be successful with the other. For example, a child may be a skilled decoder—able to read nearly any word—but may still struggle to comprehend the meaning of a story or passage. In contrast, some children may

understand a story concept when it is read to them, but struggle to decode words.

It is important for early childhood teachers to be able to understand and identify these skills so that they may be brought together in order to help children become successful readers. When children do not have basic skills necessary to support these two processes, literacy is much more difficult to achieve. In addition, there is growing understanding that content knowledge is central to helping children in decoding and comprehending text. In other words, when children understand or have information about the topic at hand, including defining key vocabulary and explaining key concepts, it is much easier for them to decode and comprehend text when they read independently.

This quick overview of reading research tells us a few important things about literacy practices in early childhood. First, in order to be successful decoders of text, children need to be able to identify letters and sounds (including blends). Second, children need lots of experiences with books to help them practice both letter identification and decoding (often just through listening and watching an adult read aloud). They need to see how books are read, to understand conventions of text, and to understand that letters grouped together make words. Furthermore, children need to see adults—teachers, parents, and community members—reading for enjoyment, to figure things out, and to make their way through the world. This base of research points to three main areas where educators can focus their attention in helping young children build strong prereading and early reading skills.

Best Practices in Early Childhood Literacy

There is now broad consensus among researchers that children need explicit experiences with learning basic literacy skills, implicit opportunities for engaging with texts that fit their abilities and interests, and teachers who can leverage these approaches into rich, interactive conversations and lessons across a variety of genres. In particular, explicit teaching strategies, such as defining words and concepts during shared book reading

and engaging in rich back-and-forth interactions about the text, provide young children with new conceptual knowledge, provide broad exposure to high-quality vocabulary, and endow them with a passion for reading. Explicit strategies also include implementing lessons where children learn letter names, sounds, and blends.

Implicit strategies support and scaffold these explicit strategies—making materials available in the environment that allow children to use their emerging literacy skills—writing and reading materials in different centers around the classroom, hands-on materials such as letter puzzles and magnets, a rich selection of books to choose and explore on their own or to bring to a teacher or family member to read together, and labels and pictures around the classroom that reinforce basic skills knowledge. This also means plenty of time to explore and read high-quality children's books across many genres; to engage with teachers in reading, instruction, and conversation; and to play with the plentiful literacy materials. Bringing together both approaches to literacy learning creates a balanced approach that gives children basic skills and many opportunities for engaging in pre-reading activities.

In early childhood, play is an area of primary importance for gaining literacy skills. Play-based experiences include times where children are directing play—choosing materials, scenarios, and actions—and other times where teachers can also engage in play to help direct activities toward certain experiences, or toward the engagement with specific materials and/or ideas. Play is a time when children often use advanced language, or imitate adult literacy strategies, such as “reading” aloud to friends or stuffed animals, or “writing” down an order in the play kitchen. A great deal of evidence exists that when literacy materials are present in play areas (such as pencils and clipboards in the kitchen areas, or books in the babies/stuffed animals area), children are more likely to practice these literacy skills. When teachers engage in play with children—often posing problems or raising new questions or ideas—play can expand to include other experiences children might not otherwise consider.

Research also highlights the important role that teacher and child interactions have in early childhood settings. For example, while reading aloud will help children develop some conceptual and vocabulary-related knowledge, several studies have shown that some explicit vocabulary instruction—where teachers define and use words in sentences with the children—can have much greater effects. However, other studies have shown that early childhood teachers tend to shy away from this type of instruction, and instead rely on more passive strategies, such as shared book read-alouds. More explicit strategies to build conceptual and vocabulary knowledge, however, are particularly important for children who are already considered to be at risk. Children living in poverty are at particular risk of being far behind their more affluent peers in terms of vocabulary knowledge. As the earlier reading research pointed out, once children are struggling readers in kindergarten, it may be difficult to change the course of their experiences. Given this knowledge, early childhood teachers and caregivers need to create opportunities for discussion with children while reading. This includes helping children learn vocabulary by defining words, modeling use of those words, and encouraging children to ask questions during shared book readings to gain better and broader understandings of vocabulary.

One other area within early childhood literacy that needs attention is the kind of texts that we choose to read with young children. Traditionally, an emphasis on literacy in early childhood settings has focused on reading more with children and using specific strategies to develop knowledge of books. Consideration of what types of texts, such as rhyming, narrative, or informational, has been secondary. However, many early childhood researchers have been recently studying the importance of information texts—texts which include nonfiction subjects rich with conceptual knowledge and vocabulary—for young children. Through broad exposure to different types of text, children have greater access to broad vocabulary and conceptual knowledge that are building blocks for well-developed reading skills.

Best practices in early childhood settings should promote research-based approaches to literacy, and teacher educators need to prepare preservice and practicing teachers to use these strategies. Primary importance should be placed on integrating access and attention to basic skills within developmentally appropriate approaches to curriculum and design of the environment. To do this, practitioners and teacher educators need to deeply consider the ways in which they are currently approaching literacy in early childhood settings, and make changes that reflect our growing knowledge of what works best for helping young children become successful readers.

Highlighting Literacy in Daily Practice

Given what we know about how children learn to read and use literacy skills in their daily lives, early childhood teachers can provide many rich experiences within the classroom. In order to meet the goal of a literate society, teachers must use curriculum that is evidence- and research-based, provide environments that are rich with print, and engage children with books, technology, and materials that promote basic literacy skills as building blocks for future learning. Some examples include the following:

- Making print visible and accessible in the classroom via hands-on literacy materials and walls that “speak” with visible literacy tools
- Teacher use of rich, complex language to define new words and use new words in everyday conversation
- Linking vocabulary and concepts through the reading of information texts
- Locating and reading print throughout the day
- Using appropriate technology to help children practice literacy skills

Working to identify these and other strategies and to implement them into the daily practice of early childhood teachers is centrally important to improving literacy outcomes for all children.

Beyond practices in the early childhood classrooms, teachers can serve as important guides and

supporters for families and communities wondering how to better prepare young children for reading. School-based literacy practices, of course, build on existing experiences that children have with literacy in their homes and communities. When families and communities are unsure of how to provide these experiences, early childhood teachers can help to highlight the ways in which print, and thereby literacy, is all around us. In addition, teachers can help families highlight the ways in which literacy is a part of their daily lives, as well as seek to better understand the ways in which families are already engaging in literacy practices. From this recognition of existing practices, teachers and families can provide mutual support to help prepare children for literate futures.

Looking Forward

As educators begin to engage with new expectations and new standards for early childhood literacy under the Common Core approach, we should all consider how best to help children engage with literacy throughout their daily lives. A focus on research-based approaches to literacy learning for young children will certainly help them make the greatest gains and prepare them for the academic challenges that lie ahead. Being knowledgeable of what research has shown us, and implementing these strategies within early childhood classrooms, is of essential importance—particularly for at-risk children.

This is of particular importance as children who are served in early childhood settings continue to come from ever more diverse backgrounds. For example, supporting the language and early literacy skills of English language learners will take special training and recognition of building literacy skills in both native and acquired languages. Similarly, children who are at risk due to poverty or family instability will need special attention from teachers in order to make sure that gaps in early language and literacy experiences are narrowed through high-quality early childhood educational experiences. To do this, early childhood teachers will have to attend to specific areas of literacy—such as helping children grow their vocabulary and conceptual

knowledge. Teaching vocabulary to young children is not without its challenges, but certain early childhood practices—such as shared book reading during morning meeting times—offer many opportunities for talking about words and using new words in new contexts.

Teacher educators and researchers must work together to take this growing body of knowledge and merge it into teacher preparation and professional development programs so that young children might have the best possible opportunities for learning to read well and with enjoyment. While this presents a challenge, it is certainly one that can and must be met within the early childhood community.

LITERACY ASSESSMENT

Literacy assessment is the evaluation of literacy skills to understand how young children are developing and performing in the domain of literacy. Literacy assessment can be formative or summative. Formative assessment is when data collected from assessment is used to “look forward” for planning purposes. It is used to provide information to educators and caregivers to support children's learning. Literacy assessments can also be summative and used to “look backward” to provide a summary thus far of children's learning at a set point in time. Literacy is a complex, multifaceted domain of development for young children and there are key areas of literacy to consider for assessment in early childhood education.

What Literacy Skills Are Important to Assess?

Literacy is just one part of a child's development and thus does not develop in isolation from other areas of development or from other domains such as math, science, and physical development. Literacy assessment must focus on key literacy skills, but in a way that applies the knowledge to meaningful tasks wherever possible. Literacy assessment should not be used to narrow the early childhood curriculum in order to focus on rote skills such as letter identification. The key areas of literacy for early childhood that should be considered for assessment are oral language, alphabetic code, print knowledge, comprehension, and writing.

Oral language includes listening comprehension, verbal expression, and vocabulary development. Vocabulary development can be separated into two distinct categories to assess: Expressive vocabulary is language that the child produces and receptive vocabulary relates to the words that children are able to understand when heard in context.

Alphabetic code consists of alphabet knowledge and phonological awareness. Phonological awareness is the awareness of the sounds of words in

learning to read and spell, and is assessed by the detection and manipulation of sounds at three levels of sound structure: syllables (e.g., ro-bot, o-pen, and rec-tan-gle), onset and rime (separating the first sound from the rest of the word; e.g., /c/ /at/ and /sh/ /ip/), and phonemes (individual sounds; e.g., /t/ /ü/ /b/ and /s/ /ö/ /k/). Phonics is connecting sounds to the letters that represent them and is related to phonological awareness. Although it may be occasionally important to assess these code skills in isolation to know the full extent of a child's understanding of letters and sounds, phonemic awareness does not need to be tested too frequently. In fact, knowing these skills in isolation does not imply that a child is able to apply the knowledge in context of reading and writing. Measures that look at the use of these skills in context are important for both assessing and instructing.

Concepts of print refer to what emergent readers need to understand about how printed language works and how it represents language and meaning. These concepts include knowing how to hold a book the appropriate way, differentiating between print and pictures, understanding that one reads left to right and top to bottom, that letters are individual units, and that letters make up words. Assessing concepts of print is best done with a text in a natural interaction between child and adult.

Comprehension of text is another key literacy skill important to assess as children develop through the early childhood years. The child's understanding of text is demonstrated through retelling and summarizing the story or information presented. For young children, this is assessed with retellings of stories using prompts from the teacher or text. For older children, comprehension is assessed by looking closely at the details of the retelling or summary that is presented either orally or in writing. These retellings and summaries develop through the early childhood years from identifying favorite books to knowing the beginning, middle, and end of a story and on to a thorough summary of material.

Writing is a combination of several early literacy skills. Children demonstrate their understanding of concepts of print, alphabetic knowledge, phonological awareness, and communication capabilities.

Therefore, assessing children's writing products is an effective way of understanding what the child knows about literacy. Writing can be divided into two concepts to assess. The first is composing or examining how the child uses writing to communicate thoughts. The other is production that evaluates how the child produces the writing such as stringing letters to form words and then working thoughts together cohesively. Writing is easily evaluated from marks on the page of a toddler to the well-written essay of an 8-year-old child. Often rubrics are used to analyze children's writing, as discussed later in the entry.

Why Is Assessing Literacy Important?

Literacy assessments are valuable for several reasons. First, teachers working directly with children must use assessment data to inform their instruction and interactions with each child. This formative assessment provides the data for differentiating instruction based on where the child is on the developmental continuum. Literacy assessments will also identify the need for special services by raising flags of concern about development or by highlighting advanced development. Second, aggregate classroom data informs teachers about the needs for the class and influences class goals that are developed based on literacy abilities of the group as a whole. Third, looking at literacy data across teachers in schools or programs provides information about professional development needs for teachers. For example, if children consistently score low or demonstrate little growth in a particular literacy skill, such as phonological awareness or writing, this may indicate that teachers need support in how to provide effective instruction and support in the identified area. Finally, literacy assessment data can be used to evaluate the impact of a program or the effectiveness of an intervention. Conducting pre- and post-assessments to compare groups that received the treatment will provide valuable information about the effects of the intervention.

Literacy skills are critical to present and future learning as literacy transcends all learning domains. Examples of this transcendence are applying

writing skills for science journals, using reading skills for understanding math word problems, and relating vocabulary development to social studies understanding. Early literacy skills have been shown to have moderate to strong relationships with later literacy skills such as decoding, comprehension, and spelling. There is strong evidence that early precursors to literacy such as alphabetic knowledge, phonological awareness, concepts of print, and writing are highly related to later literacy proficiency. Although important, the relationship of these “code skills” with later literacy learning should not overshadow the importance of language and comprehension development in the early years.

Literacy develops rapidly during early childhood. For instance, children develop from infancy to oral language, recognizing several letters and actively engaging with text in 2 to 3 years. From kindergarten through second or third grade, young children develop from identifying letters and sounds to reading texts fluently. Assessment of early literacy skills and development provides necessary information to teachers, parents, caregivers, and other adults about this rapid development and can flag concerns about a child’s literacy development.

How to Assess Literacy

Just as there are many uses for literacy assessment data, there are multiple methods of assessing literacy. The variety of methods fulfills specific purposes for data use provided by each assessment approach. Some methods are formal and others informal, but all can be used to obtain information about the literacy development of young children. Assessments can be administered on-demand as one snapshot of a child’s literacy ability or data may be collected over a specific time period to evaluate literacy skill development.

Screening assessments are used to determine whether skills are progressing as expected or when there may be a need to further investigate. Screenings are generally examinations of basic developmental skills, such as phonological awareness, that are implemented to flag concerns and indicate when further assessments are needed. Diagnostic

tests provide a specific in-depth look at literacy skills for decision making about remedial instruction or special services. Formal standardized tests of literacy that are norm referenced provide a look at children’s skills compared to similar-aged peers.

Standards-based literacy assessments relate to key learning benchmarks, assisting early childhood teachers as they plan for literacy instruction. Observational assessment is one type of standards-based data collection. Teachers or caregivers observe children over time and record evidence of their learning in the natural environment. Literacy development rubrics are valuable scoring tools that identify specific criteria to be met. Rubrics show the developmental continuum of various literacy skills such as writing or vocabulary. Checklists and rating scales that are based on developmental expectations and are completed by teachers or caregivers provide a quick appraisal of a child’s skills.

Considerations

Reliability and validity of assessments are critical components to consider in literacy assessment. Reliability is the consistency of the measure. If an assessment does not produce consistent results then the results are not likely to accurately reflect a child’s literacy development. Validity of an assessment is the extent to which the assessment measures what it purports to measure. For instance, an assessment of reading comprehension should be an accurate measure of children’s understanding of text and not be clouded by other skills such as vocabulary. Validity can be measured in several ways. Concurrent validity is how the assessment relates to similar assessments. Content validity is the degree to which the scores yielded by a test adequately represent the content. Predictive validity is the degree to which the predictions made by an assessment are confirmed by later behavior. All forms of validity are important to consider when using literacy assessments.

Another consideration when selecting literacy assessments is for the assessment to be culturally and linguistically appropriate for the targeted audience. This is to say that assessments should be free of bias with regard to language or culture.

Assessing children in their native language whenever possible provides the most accurate picture of a young child's literacy understanding.

Lastly, it is best to obtain several measures of children's literacy development before making high-stakes decisions. This includes making judgments about services for a child or the continuation of a program or intervention. Collecting sufficient data to have confidence in the decisions made is necessary.

literacy skills. Classrooms that provide children with a high-quality literacy environment are carefully arranged and contain a variety of literacy-enhanced props that refer to tangible literacy materials or resources (e.g., books, writing tools). Scholars such as Lee McGee have found that literacy-rich classroom environments for young children are rare. This entry discusses how early childhood educators might create classrooms that support literacy for young children by inserting literacy-enhanced props into their classroom environments.

Literacy-enhanced props include narrative and informational books, print props (e.g., posters), and writing tools and materials. A collection of high-interest children's books influences the nature of children's literacy activities and fosters their literacy skills. McGee suggests that almost all early childhood classrooms have narrative books, yet lack books constituting other text genres such as informational books. Early childhood educators consider the following two criteria for the selection of books to enrich literacy props in their classrooms. First, books need to represent different genres such as narrative, informational, alphabet, poetry, and concept books. A variety of book genres can address children's variety of interests as well as motivation to read while promoting their literacy development. Second, books should range in the level of difficulty from simple to more complex texts and relate to the current theme as well as ongoing learning activities that take place in the classroom routine. For example, if the class was studying weather, then narrative (e.g., *Freddy the Frogcaster*) and informational books (e.g., *How Does Weather Change*) connected to this topic should be included. When a new topic (e.g., plants) is introduced, the old sets of books related to the previous topic can be replaced with new ones.

Print props (e.g., posters) are another type of literacy-enhanced prop that can help children discover how spoken words can be represented in print. McGee suggests that early childhood classrooms provide children with only basic print props (e.g., lists, calendars) that may not be powerful enough to facilitate literacy learning. Three more

LITERACY-ENHANCED PROPS

A high-quality classroom literacy environment can positively support young children's emergent

higher-level and engaging types of print props are alphabet word walls, informational displays, and commercial posters. Each of these print props is described next.

Alphabet word walls refer to a display, either on the classroom wall or on a board, that consists of large uppercase and lowercase letters in alphabet order with words that begin with each letter listed below them. The words on the word wall might come from children's names, stories, songs, rhymes, or poems used in the classroom. Informational displays show specific items and include labels (e.g., cubbies labeled with children's names), lists (e.g., birthday charts), directions (e.g., classroom rules), schedules, message boards, and calendars. Finally, commercial posters refer to charts, graphs, or other displays bought at educational supply stores that provide accessible print models for children (e.g., poster that labels colors). When selecting these print props, early childhood educators should (a) determine what function the props serve in the environment (e.g., to inform children of the day's activities), (b) make plans for using these props in everyday school activities, and (c) make sure these props are visible in the classroom.

Writing tools and materials can promote a variety of writing experiences. Early childhood educators might enhance literacy materials related to writing by including the following writing tools and materials in their classrooms: different kinds of paper (e.g., lined paper, unlined paper); writing utensils such as pencils, markers, chalk, and magnetic styluses; writing folders for keeping children's writing products; a chalkboard or dry-erase board; writing worksheets or workbooks; writing portfolios; or a bulletin board for displaying child-generated writing, child-dictated writing, and examples of different forms of writing such as letters. In addition, technology is increasingly recognized for its potential to support children's literacy learning as a writing tool. For example, Douglas Clements and Julie Sarama suggest that young children who use word processors do not worry about making mistakes, have fewer fine motor skills, and enjoy writing. Consequently, early childhood educators might consider providing a variety of technologies

that children can explore and use for writing (e.g., computer, word processor, software packages) in their classrooms. As Susan Neuman and Kathy Roskos recommended, while stocking the classroom with writing materials and tools, early childhood educators should determine if these materials and tools can be used naturally and safely by young children. Several writing tools such as pens or pencils with fairly sharp points can be provided only when educators are available to monitor children's use.

Most importantly, every center in the classroom should be enriched with literacy-enhanced props. With careful thought and planning, literacy-enhanced props such as narrative and informational books, print props (e.g., posters), and writing tools and materials can be incorporated in all areas of the classroom including the classroom library, dramatic play, building, and science areas to support children's literacy explorations.

LOOPING

Looping, also called multiyear teaching, multiyear placement, or student–teacher progression, is the practice of having a teacher promoted with his or her students over a period of years. Most often the “loop” is two or three years in duration. This is most common in primary and preprimary education, particularly during transitional developmental periods (e.g., first–second and sixth–eighth grades). Over the years, looping has gained in popularity. This entry provides a brief overview of the origins of looping, discusses research that informs our understanding of the outcomes associated with looping, and identifies some potential challenges of looping.

Origins of Looping

The use of looping as an intentional practice in education had its origins in Waldorf education, which began in Europe and was brought to the United States in 1928. Prior to that, looping in the United States was most often found in settings where additional teaching staff or classrooms were not available (e.g., one-room schoolhouses), which rendered looping an educational necessity. In contemporary settings looping is common in some countries (e.g., China, Germany) and may be also found in educational contexts where resources are limited, such as developing countries or rural settings. Certain educational philosophies, such as Waldorf and Montessori schools, also incorporate looping into their educational approach. In the

United States some schools use looping or multi-year classrooms as part of their standard educational practice.

Looping is found throughout the world and educational span. For instance, China has been using looping as students transition to new school settings—primary, middle, and high schools. Preschools in Italy rely on a 3-year looping cycle, with students staying with the same teacher and peer cohort throughout their preprimary years. Within the United States looping has experienced periodic increases in popularity over time and educational history, with use primarily focusing on the early years of education. Different goals and considerations are typically invoked as the rationale for the use of looping across different stages of education.

Outcomes Associated With Looping

Research has revealed that students in looping classrooms benefited academically by remaining with the same teacher and classmates for successive years. Proponents of looping often argue that looping allows for developmental differences by gender, disability status, and individual variation in a way that is not possible when students are promoted to the next grade after just 9 months of instructional time.

Studies have reported that looping has potential social benefits for students, including more time to establish positive peer relationships and increased opportunities for shy students to develop self-confidence. Other research reports that looping helps teachers to understand the needs of individual students and allows for more sustained classroom relationships. In addition to potential academic benefits, teachers, parents, and administrators have generally endorsed looping practices. Other positive outcomes associated with looping include improved student confidence, more stability, stronger student–teacher relationships and an increased sense of belonging. Research has also revealed that looping supports continuous learning, helps minimize retention, and avoids the need to start from scratch each year.

Multiple studies have looked at looping classrooms to explore academic and social outcomes. A

comparison of preschool children in looping and traditional classrooms found that students in looping classrooms performed better on personal and social development but lower on mathematical thinking. Among elementary students some studies have found that students in looping classrooms had significantly higher academic performance in both reading and math. Additionally, students in looping classrooms have been found to have significantly better attendance and lower rates of retention than students in comparison classrooms. Some evidence has suggested that looping may have particular benefit for at-risk children or those children with less stability at home.

Challenges of Looping

Challenges in looping can and do occur. Students could be placed with an ineffective teacher, or highly effective teachers could be assigned a troublesome group of students. Sometimes, students in looping classrooms are together for too much time and peer interactions become wearisome or take on a sibling-like quality. Even if teachers and students are not problematic in their own right, student-teacher mismatches can result in a dynamic that does not benefit either the student or the teacher. Additionally, looping poses challenges for newcomer students entering mid loop and for the whole cohort when the time comes for them to transition out of the loop.

Teachers may also struggle with the challenges of looping classrooms, particularly the need to be familiar with and prepared to teach multiple years of curriculum. Even effective teachers inevitably have areas of weakness that may get magnified when perpetuated for students in their class over multiple years. Ineffective teachers are even more problematic and may leave students with lapses in their learning that are difficult to overcome. Even so, there is strong evidence that looping can be a highly effective strategy for teaching and learning.

Conclusion

Looping is an educational practice with historical roots in one-room schoolhouses and the Waldorf

approach to education. The idea of continuing to keep students with the same peer cohort and teacher over time is used around the world at various grade levels, for students from preschool to high school. Looping has been touted as a good education practice for reasons ranging from providing a more developmentally appropriate context to improved academic outcomes. While challenges, such as poor student-teacher fit, have been relayed as concerns of looping, the majority of evidence supports this practice. Nonetheless, looping remains the exception, rather than the norm, in American classrooms. Despite this, looping continues to be an educational option that may offer some advantages for those seeking additional methods for successful outcomes in early childhood education.

M

MASTER TEACHERS

Master teachers in early childhood settings include those who teach and care for infants, toddlers, and children younger than 5 years old. Frequently, these educators and caregivers work outside public schools, most often in child care, Head Start, or nursery school settings. Notions of mastery in early childhood care and education settings go beyond proficiency in academic disciplines to include a knowledge base in developmental psychology, family systems, and curriculum development while understanding how to meet the needs of diverse populations through observation and assessment of young children's behaviors. The master teacher is also considered a leader and a mentor to his or her peers.

Dispositional Attributes

Dispositions, or habits of mind, include attitudes, professional behaviors, ethics, values, beliefs, and perceptions, and are of a psychological nature, yet do not remain hidden. They are manifest in a teacher's actions. Master teachers display dispositions embodied in their communication skills, their development of nurturing environments, reflective teaching, and the ability to participate in reflexive dialogues. Additionally, attention given to moral and ethical aspects of caring for and educating

diverse young children is a disposition displayed by the master teacher.

While it can be said that many of the interpersonal skills required of excellent teachers are necessarily found in all classrooms, often the relationships between caregivers and teachers of young children and the children and the families with whom they work are different from those found in elementary and certainly secondary school settings. Master teachers of the very young are expected to present a steady flow of information to the family regarding their child's experiences outside of the home. Those who care for and educate infants and toddlers are responsible for daily reports to family members, notating behaviors, developmental milestones, and physical needs that were met. The master teacher of preschool children continues this open line of communication to families, often in the form of written narrative reports. These include descriptions of the child's evolving academic or content area interests, social interactions and emotional well-being, language development, creative and aesthetic encounters, and physical development.

Master teachers of the youngest children are adept at what Nel Noddings calls ethical caring. They respect the individual child, coming to know each child's funds of knowledge, interests, and abilities. Master teachers consider the young learner to be a child first, seldom using the term "student" in the traditional and hierarchical sense

of the teacher–pupil relationship. While empathetic, master teachers do not assess children from a deficit standpoint in which a child's absence of understanding or yet-to-be-developed skills drive instruction. A master teacher considers himself or herself a coinvestigator and facilitator in dialogue with the young learner.

Dispositional attributes found in master teachers are also evident in their ability to reflect on their own teaching practices. As defined generally by John Dewey, and later, speaking more specifically of teachers, by Donald Schön, the excellent educator is adept at reflecting on experience by reflecting-in-action and reflecting-on-action. The skilled teacher consciously thinks about the interaction and experience of the child while in the act of teaching, or after observing and assessing a child's learning experience. The gifted teacher who is dedicated to fairness and equity then reflects-for-action, and plans further curricular experiences that may include his or her own active engagement in changing ineffective or detrimental educational policies, and working toward social justice.

Master teachers are accessible, caring, and enthusiastic. They are welcoming to children and families, peers, and their own mentors. Often this approach to teaching and learning leads the master teacher to mentor others. Master teachers' enthusiasm lends itself to the caring community they have nurtured in the classroom, and easily attracts other adults to want to learn from them.

Knowledge Base and Formal Education

Master early childhood educators possess a deep commitment to lifelong learning. They are interested in the world around them, and they know that in order to present features of this world to the children in their care they must condense and interpret them in ways that young children can comprehend. They are therefore willing and eager to acquire new knowledge regarding a range of subject matter. They are committed to responding to children's interests by developing their own eclectic knowledge about the query. Master teachers model investigation and discovery while offering

children appropriate experiences in which they can experiment, question, imagine, and decide.

Expert early childhood educators possess a professional knowledge base. Besides acquiring content knowledge, they have examined child development, inclusive and multicultural methodologies, and appropriate assessment to understand how to engage young children. The master early childhood educator then understands how to adapt content knowledge into pedagogy appropriate for the individual child, and for the culture and setting in which the learning takes place.

Master teachers' knowledge of content area methodologies allows them to teach curricular objectives through meaningful experiences for young children. Through differentiated and individualized instruction based on a deep understanding of how young children learn, the expert modifies his or her approach, refines his or her language, or adds materials to help the child achieve success and mastery. Therefore the master teacher develops learning goals that are developmentally and culturally appropriate.

Master teachers may use child-centered approaches as well as teacher-directed instruction when necessary. They are versed in pedagogies that meet the needs of the typical as well as the atypical learner. They will draw on their knowledge of learning theories and educational philosophies, curricular models, and instructional approaches to make the best fit for the child within a particular care and education setting. The master teacher therefore teaches intentionally and sets learning goals, as compared to performance goals, for both the group and the individual child.

Approaching learning from an inquiry standpoint, the early childhood educator understands that exploration and discovery drive deep learning, and therefore observes and assesses children's interests and nurtures an emergent curriculum to match. Often using a project approach, master early childhood educators ensure that all content areas are integrated into the work around a given subject of study. They have learned how to ask good questions—those that probe children's prior knowledge and current understandings, and promote activity and reasoning. They offer hands-on

experiences that allow children opportunities to discover and form their own ideas through active participation. Master teachers value “wrong ideas” for their contribution to understanding what something is or is not. Importantly, they schedule enough time for these investigations and understand the importance of repetition. They are, above all, skilled at guiding and instilling in young children the dispositions to become active and lifelong learners through the use of conjecturing, observing, categorizing, theorizing, investigating, and making and sharing meaning.

Master Teacher as Mentor

The expression *master teacher* also indicates someone whose role it is to provide coaching and mentoring to other teachers, usually those new to the field. Therefore, it is important that master teachers participate in ongoing professional development so they can become skilled in recognizing and embodying the qualities necessary for a successful mentored relationship. Master teachers who serve as mentors of novice early childhood caregivers and educators should have numerous years of experience working with young children in group settings. They should embody the attributes listed earlier and be in what Lilian Katz describes as “the mature stage” of their teaching careers. They will therefore be squarely situated in their own practice, seeing themselves as professionals who take a philosophical as well as a practical approach to the work of educating and caring for young children.

While master teachers’ expertise in early childhood pedagogies is important, they must also be knowledgeable about the needs of the adult learner and practice appropriate principles of supervision in educational settings. These include, but are not limited to, awareness of adult learners’ need to know why something is of value to be learned *before* they learn it. The master teacher must also support the adult learner’s self-concept as being responsible for his or her own learning. Adults come with a wide range of experiences that influence their responses to educational techniques and situations. Therefore, as he or she does with young

children, the master teacher should engage in a process of mutual inquiry with the adult learner. Along these lines, the master teacher as mentor will recognize the adult learner as someone who has a life-centered orientation to learning and will plan ways to help the learner apply the new information to real-life contexts and relevant situations.

The master teacher knows that good mentoring relationships are built on mutual comfort and respect. He or she understands how a trusting relationship will allow both participants to be open to ideas, practice reflection, and welcome dynamic assessment. Master teachers who are ready to mentor others have by this time examined their interactions with their peers, their administrative and managerial styles, and their own professional ethics. And, since master teachers are proficient in reflecting on their own teaching, they have cultivated a consciousness regarding their own beliefs and experiences pertaining to race, gender, class, sexual orientation, and ability. Therefore, they will be in a better position to demand a critical and honest reflection from their mentees.

By scaffolding and contextualizing the mentee’s education, the master teacher will also be prepared for occasions when the learner relies on “customary” knowledge—or information handed down as “The Truth.” Because they can trust their own insights into contextualized learning, master teachers know that “settled knowledge” is only one component of the countless ways of experiencing knowledge, and will take steps to challenge societal definitions that may constrain both their own and the mentee’s development.

The master teacher as mentor will enact supervision, not evaluation. He or she will observe and listen. He or she will arrange teacher meetings that not only allow peer observation, but also develop coaching and mentoring protocols for future mentors. By modeling instructional strategies and ways to document children’s learning, the master teacher as mentor will assist the novice teacher in ways to gather objective evidence to assess children’s development in all areas of growth.

If working with a group of educators, a master teacher will practice and support reflexivity.

Reflexivity occurs when participants are aware of the shared nature of reflecting, including who is present, who “has voice,” and who may be silent. In understanding that learning is always influenced by the setting in which that learning takes place, the master teacher as mentor will ensure that everyone in the group is willing to learn from one another’s perspectives and experiences. He or she will also help participants locate and use reflexive practice as a resource from which they can move toward defining and enacting their visions of excellence in teaching.

Finally, master teachers will participate in their own ongoing professional development by engaging with other mentors or coaches and educational specialists to improve their work. They will have attended high-level professional development workshops and conferences that address the roles of the master teacher or mentor, so that they may have a positive impact on the school environment by conveying new ideas to their mentees.

MATERNAL WORK STATUS

Maternal work status is a key family factor that is linked with young children’s education. Does having a mother stay at home benefit the early development of her children? Does having an employed mother pose a risk for early child development or confer benefits? These questions have dogged the field of developmental psychology because they trigger concerns about the effects of maternal deprivation on children and raise issues about socialization processes that are essential to children’s cognitive and social development. At the same time, however, maternal employment provides opportunities for increased economic resources and enhanced adult well-being. Implicitly, questions about maternal employment when children are young tap into values and attitudes about the roles of women in society and beliefs about best child-rearing practices.

Well-studied and most controversial is maternal employment during children’s first 3 years, a time considered particularly sensitive for brain development. Complicating attempts to draw conclusions about maternal work in relation to early child development are varying definitions of employment, varying research designs, varying child outcomes, and the moderating influence of contextual factors. All these factors are explored in detail in this entry.

Definitions of Work Status

An interesting duality that persists even today, for academic and lay persons alike, is the fact that

mothers being employed is controversial, whereas for fathers, it is their being *unemployed* that is controversial. Viewing mothers as employed or not has been criticized for being a mere “social address” or “empty set, bereft of any structure or content” (Bronfenbrenner & Crouter, 1982, p. 41). Nonetheless, this dichotomy has continued to characterize much of the research on maternal employment. Particularly concerning to many is full-time employment; the Bureau of Labor statistics define full-time work as 35 or more hours per week. Researchers who study maternal employment have used boundaries that range from 30 to 40 hours per week. Sometimes employment is trifurcated into full time, part time, and nonemployment. Officially, part time is 1 to 34 hours per week. In research, the high end for part-time maternal employment co-varies with the cut-off for full-time work; at the low end, some researchers set a minimum such as 5 hours per week. Still others divide part-time employment into low and high. It is difficult to compare “apples to apples” when the categories change across studies.

Varying Research Designs

When studying maternal employment and child development, random assignment is not possible. Although researchers may use words such as *effects*, *influences*, and *consequences*, most study designs concerning maternal employment are correlational and rely on single time measurements. In these types of studies, children of a certain age whose mothers are employed are compared on some dimension to peers whose mothers are not employed. Stronger designs are longitudinal, the best known of which are the National Longitudinal Study of Youth and the National Institute of Child Health and Human Development (NICHD) Study of Early Child Care and Youth Development. These two large datasets have been the basis for numerous articles and monographs on early and later maternal employment in relation to concurrent and later aspects of child development.

Studies also vary in the type of instruments used, ranging from maternal questionnaires and

interviews to teacher reports to third-party assessments using standardized tools as well as structured and unstructured observations of young children. Although most studies position maternal employment as the independent variable, bidirectional pathways exist, whereby characteristics of the child, such as health, influence maternal work activities.

Varying Child Outcomes

Many facets of child development have been studied in relation to maternal work status, including social relational (e.g., attachment, peer relations), cognitive (including achievement), physical and mental health (e.g., obesity, depression), gender (including roles and ideology), and behavior (including positive and problem behaviors). Most relevant for early child education are cognitive/achievement-related outcomes, which build on prior knowledge and experiences and may be particularly vulnerable to environmental influences. Rachel G. Lucas-Thompson, Wendy A. Goldberg, and JoAnn Prause’s 2010 meta-analysis of five decades of studies on maternal work status during early childhood and children’s achievement produced mostly nonsignificant effect sizes; however, a notable exception was the small, significant main effect between early maternal employment and teacher ratings of higher achievement.

Contextual Factors

Mothers’ work is a contextual factor from the point of view of the child, and work itself is embedded in a larger social context. The study of mothers’ employment compels us to consider linkages among the settings of home, school and child care, and the workplace. Important to early childhood education is how well those linkages are functioning. Practices and policies in the macro environment have an impact on the quality of the connections among the major settings in mothers’ and children’s lives.

Significant moderators of the associations between maternal work status and child outcomes,

based on single studies and meta-analyses, include one- or two-parent family structure, socioeconomic status, alternate care arrangements, child gender, mothers' satisfaction with work, timing of return to work, workplace characteristics, and fathers' employment. For example, in the meta-analysis by Lucas-Thompson and colleagues, there were small, positive effects for achievement when families were at risk economically, but small negative effects when families were middle class or upper class.

The association between early maternal employment and performance on formal achievement tests was small and positive for one-parent families but small and negative for two-parent families. When adjustments were made for child care, associations between early maternal employment and IQ test performance were negative but nonsignificant with other aspects of achievement. In terms of the timing of maternal employment, the meta-analysis found small, negative associations for achievement when mothers worked in the child's first year, but small, positive linkages when they worked in years two and three. Other research has shown that the intensity of maternal employment during the child's first year is particularly important.

Maternal work status is an important factor to consider in relation to early child development, but it does not operate alone. Study characteristics and contextual factors must be considered when evaluating the connections between maternal employment and early childhood education/achievement. Finally, employed and non-employed women often differ on a variety of measured and unmeasured socioeconomic, demographic, and psychological characteristics that may cause selection bias and account for some differences in child development that, if left uncontrolled, could erroneously be attributed to maternal employment.

MATURATIONAL THEORY

Arnold Gesell (1880-1961), a pediatrician and psychologist, is the theorist most associated with the maturational theory of development, even though Jean-Jacques Rousseau (1712-1778) first mentioned nature's inner plan or timetable. The primary characteristics of the maturational theory include the following:

- The child develops biologically in a predetermined order from within, unfolding in fixed, predictable sequences or stages.
- Every child goes through the same series of fixed sequences, but each child has his or her unique rate or pace.
- The child is a product of his or her environment, but playing a larger role are genes and human nature: heredity (body type), temperament, culture, health, and intelligence.

The process of biological maturation actually starts at conception with the fertilized embryo. While the cells are rapidly dividing and reproducing, every child develops in the same way: first the central nervous system, then the head, heart, arms, and legs. Likewise, after a child is born the same sequence of development will occur in every child: first the baby gains control of lips and tongue, then

eyes, then head. Next to develop are arms to push up and grab things, rolling over, sitting up, standing, and walking. Both the prenatal and postnatal development happens in a head down to feet (cephalocaudal) process.

Concepts related to the maturational theory are reciprocal interweaving, functional asymmetry, self-regulation, and individuality. Reciprocal interweaving explains how humans who have many instances of two simultaneously developing matching parts of the body (eyes, brain hemispheres, legs, etc.) reach an effective organization of the two. An example of this is handedness. First the child explores one hand, both hands, and the other hand, and eventually settles on preference for one hand over the other.

Functional asymmetry in some ways contradicts this explanation of reciprocal interweaving. While balancing the dualities of hands, eyes, and so on is characteristic of human development, in some cases a degree of asymmetry enhances effectiveness. An early example of this is the infant's tonic neck reflex that is seen primarily in the first 3 months. Infants, when in the supine position with head to one side, will have one arm outstretched and the opposite arm flexed. A later example in development is stepping forward on the right foot while throwing the ball with the right arm.

Self-regulation is the intrinsic ability to maintain a level of equilibrium and overall integration. It is demonstrated even in newborns who, when allowed, regulate their own development by determining their own best schedules for eating, sleeping, and being awake. Older children develop the ability to control themselves and inhibit competing stimuli when confronted with many choices.

Finally, individuality refers to the notion that each child has his or her own pace and development and that each child is unique due to his or her combination of genes, body type, temperament, culture, health, intelligence, and environmental experiences.

According to Gesell's maturational theory, growth and development should be thought of as a cyclical spiral alternating between patterns of equilibrium and disequilibrium, each cycle of the

spiral encompassing the time it takes to move through six stages that alternate between equilibrium (E) and disequilibrium (D). Gesell's cycles of development, and six well-defined stages, are repeated throughout life. One cycle includes the following six stages: smooth (E), break-up (D), sorting out (E), inwardizing (D), expansion (E), and neurotic "fitting together" (D). During the 2 to 4½ year age period (one cycle), each of the six stages lasts about 6 months; but passing through stages is faster in the early months of development and slower in the later months.

Gesell's research also established normative trends for four areas of growth and development, namely (1) motor, (2) adaptive (cognitive), (3) language, and (4) personal-social behavior. Originally published as the *Gesell Developmental Schedules* in 1925, these developmental schedules, most recently updated in 2011, continue to serve and guide pediatricians and psychologists throughout the world today.

Critics of the pure maturational theory call it too simplistic and naive, and point to the indisputable role of the environment and the role of teaching and learning that Gesell viewed as unnecessary hurrying of the child. Maturational theory also emphasized nature over nurture as a determinant of child development. The nature versus nurture "controversy" continues to be discussed; however, experts agree that development is a dynamic process of the mixing of both environment and individual human biology. Critics also challenge the "norms" as being too confining to use with all children and have presented studies of newborns that have abilities that seem to be beyond expectations set by Gesell's norms.

In conclusion, since the maturational theory cannot be empirically proven or disputed, it is best to recognize what the maturational theory has contributed over time to the big picture. Responding to the child's attempt at self-regulation is the basis of today's child-rearing practices. Recognizing how each stage of development has definable characteristics and behaviors leads educators and parents to have appropriate expectations. This also has led to the commercial labeling of toys as

“Appropriate for ages X to X.” Further, maturational theory explains why sooner is not better, but rather that it is simply a developmental difference when a child performs a task before others his or her age. Children who learn to walk at 10 months are not better walkers than those children who learn at 14 months, nor is this difference predictive of children's later motor abilities. Gesell's maturationist theory of stages of development has served as the basis for later stage theories, such as Jean Piaget's theory of cognitive development.

MEASUREMENT, CHILDREN'S UNDERSTANDING OF

Measurement is a mathematical knowledge domain that involves the assignment of a numerical value to a measureable attribute of an object or event. Measurement enables the ordering and comparing of objects and events that are not separately countable. The term *measurement* not only represents a range of mathematical concepts, but it is also a mathematical process (i.e., measuring), whereby the measurement of an object or event is made. This entry provides an overview of children's measurement development, information about the foundation measurement concepts and processes, and an explanation of the different measureable attributes in mathematics.

Overview of Measurement Development

Research has shown that children begin to develop understandings about measurement from a young age. In particular, the research of Douglas Clements has demonstrated that young children are aware of measureable attributes, even though they may not yet be able to quantify or measure them accurately. Young children have an ability to compare and make judgments about quantity, albeit in an informal sense. Most young children know that if they have a quantity of an item, and then they are given more of that item, they have more than they did before. There is much research that shows that most children are able to compare two or more objects and make judgments as to which is the larger or smaller of the group. Young children reason about quantities, including recognition of equality and inequality, and use language to describe quantities and attributes.

A commonly held view is that children's measurement knowledge develops at two levels: *emergent measurement* and *proficient measurement*. Emergent measurement involves children using measurement for their own purposes, representing measurements in ways that make sense to them. Proficient measurement, however, requires comprehension of measurement concepts and processes, and the ability to use this knowledge in flexible, accurate, and efficient ways.

Measurement Concepts and Processes

Learning about measurement and the measuring process involves three key concepts: (1) objects and events have attributes that can be measured, (2) measurement can be used to compare objects and events, and (3) both informal and formal units can be used to measure objects and events.

Measureable Attributes

Measurement development is based on the recognition that objects and events have measureable attributes and that these attributes can be labeled in particular ways. Measureable attributes of objects and events include length, area, volume and capacity, weight and mass, time, temperature, and value/cost (i.e., money).

Length refers to how long something is, whether along a single plane or through two dimensions. Length is the generic term associated with all linear measurement, but linear attributes also include *height*, *width*, and *depth*.

Area refers to the amount of space contained within a two-dimensional shape. A good understanding of linear measurement is prerequisite to area measurement, as the measurement of areas requires the iteration of units in two dimensions.

The term *volume* refers to the amount of space taken up by an object, while the term *capacity* refers to the amount an object can hold. The two attributes are typically developed in tandem as children explore the filling and emptying of objects.

Mass and *weight* are terms that are often used inappropriately, or are incorrectly viewed as interchangeable. Mass refers to the amount of matter in an object, while weight is the term used to describe the force that gravity exerts on an object.

Time is the concept that events occur in a temporal order and have duration. It is an abstract concept that is often quite difficult for young children to grasp. However, there is research that demonstrates that even very young children can engage with concepts of time when they are connected to meaningful everyday experiences.

Temperature can be defined as the warmth or coolness of an object or substance. Temperature is often overlooked by curricula as a measureable attribute; however, it has all the same features as the more commonly recognized measureable attributes, including the ability to be ordered and compared, and the assignment of both informal and formal units of measurement.

Value is another measureable attribute that is often overlooked. However, it is important for children to recognize that objects and events have values that can be measured, and that *money* is a system of formal measurement units.

Comparison

Measurement can be used to compare objects and events. Typically, children first learn to compare by identifying the same attribute in different objects. Children then make judgments about the objects on

the basis of the common attribute. Making judgments can occur by placing the objects against one another, usually along a common baseline. This is known as *direct comparison*. Comparisons between objects can also be made *indirectly*, usually by using another item as a referent.

Units

Units of measurement are tools that can be used to calculate and communicate measurements. Units are used in different ways in different contexts to suit different purposes. In general, the application of units involves identifying a unit of measure, then subdividing the object by that unit, placing the unit end-to-end. This is known as *unit iteration*. This process applies regardless of whether the unit being utilized is formal or informal.

Conclusion

Children's measurement development typically involves understanding three key concepts and processes: recognition of measureable attributes, comparison, and application of informal and formal units. There is much research evidence that children develop measurement knowledge from a young age.

MEASURING EFFECTIVENESS

Measuring effectiveness refers to the systematic collection of data to examine whether a program has achieved its goals. Depending on the program's maturity and funding source, the effectiveness of an early childhood program may be examined for different reasons. For a new experimental program, research on effectiveness examines whether the program is capable of achieving its intended outcomes. Programs that are well established examine effectiveness with the goal of improving over time. Policy makers and funders often are interested in the effectiveness of established programs for purposes of accountability.

While the motivation to measure the effectiveness of programs varies, it is an important activity across the full spectrum of early childhood programs. These programs include public preschools, home visiting programs, Early Head Start and Head Start, child care, and early intervention and preschool special education. Public funds support many programs for young children and their families; policy makers and taxpayers want to know that their investment in these programs is achieving the intended outcomes. Equally important, children and families participate in these programs with an expectation of achieving certain benefits, and it is important that they realize these benefits. This entry discusses the similarities and differences in measuring effectiveness for the following three purposes: knowledge development, program improvement, and accountability.

Knowledge Development: Determining the Potential Effectiveness of a New Program or Intervention

Researchers make a distinction between efficacy and effectiveness studies. Efficacy refers to studying

an intervention or program under optimal conditions. Efficacy studies look at whether something can work. Effectiveness studies look at whether something works in real-world conditions. At the efficacy end of the continuum are well-defined studies of new activities intended to improve one or more child or family outcomes. Examples include a study on a new curriculum for a preschool classroom, such as a literacy curriculum; an evaluation of a media campaign designed to increase the amount of time parents spend reading to their toddlers; and a study of an intervention designed to improve a child's communication skills. On the effectiveness end of the continuum are studies that examine outcomes of large-scale early childhood programs such as the statewide prekindergarten program in Oklahoma or the Abbott preschools in New Jersey. For ease of discussion, *effectiveness* is used in this entry to describe the focus of any study intended to determine whether an activity or a program produced positive outcomes for children, families, or both.

Designing innovative activities and interventions as well as studying their impact on outcomes is likely to be undertaken by university-based researchers. The research team might spend many years developing and refining the curriculum or intervention based on a series of small studies. To determine the effectiveness of a new curriculum, the researcher would identify the intended outcomes and select or develop measures of those outcomes. For example, if the curriculum was designed to improve children's literacy skills then the researchers would identify methods for assessing literacy skills. Groups of children or sets of classrooms would be assigned to receive the curriculum, and there would be a comparable set of classrooms that would not receive the curriculum. Ideally, which set of children receives the curriculum would be determined by random assignment with one or more groups randomly assigned to receive the new program and the other groups excluded from the initiative. The study also might include measures of how well the curriculum was implemented. The study would look at the data for those who received the curriculum and those who

did not, and reach a conclusion about whether the children who received the experimental curriculum performed better than those who did not. Based on the findings, the curriculum developers could modify the curriculum and collect more data, or they might want to examine the curriculum's potential to achieve its outcomes with a different group of children or in different localities until its effectiveness has been thoroughly documented. At this point, the curriculum could be disseminated to a variety of classrooms as having been shown to be effective. In reality, very few curricula or interventions in use in early childhood programs have been examined this thoroughly across a range of conditions; but if they were, teachers and program administrators would be able to make more informed choices about what to implement.

A more complex examination of effectiveness involves looking at the effectiveness of an entire program. Programs are likely to have multiple goals to address a particular social problem. An example is a home visiting program for teen mothers to teach them how to promote their babies' development and to support them in finishing high school and preventing another pregnancy. Another example is a comprehensive preschool program that provides children with access to medical and dental services along with a full-day classroom program and works with parents to help them support their children's learning. Because programs like these have multiple goals, examining their effectiveness requires collecting and analyzing data on the intended outcomes associated with each of these goals. The findings might show the program was successful in achieving some of its goals but not others. Like the simpler curriculum example, the ultimate objective is to demonstrate the effectiveness of the program so the model can be disseminated and replicated more broadly.

Early childhood education offers many examples of programs that have been studied and found to be successful in achieving one or more of their intended outcomes. Two of the most famous are the Perry Preschool Project and the Abecedarian Project, both of which involved providing intensive preschool experiences along with other supports to

young children from low-income families at high risk for low academic achievement. These children were in preschool several decades ago and the researchers have been able to follow the children into adulthood. Although not all intended outcomes were shown to be achieved at all of the time points when the measurements were taken, these projects were able to demonstrate that participating in the program made a significant difference in meaningful outcomes, such as decreased likelihood of incarceration and increased employment, for those who participated compared to those who did not. These kinds of outcomes were not the original goals of the program, but they were achieved nevertheless.

The findings from these studies have been cited repeatedly in policy papers as evidence that providing preschool can make a difference in children's lives. There is no question that these studies produced strong evidence, but what gets lost in the discussion is that "preschool" comes in many varieties. These studies did not examine all possible variations of preschool. Each studied a very intensive, high-quality, well-resourced program that undeniably produced impressive results. These studies have been incredibly important for demonstrating that high-quality early childhood programs have the potential to make remarkable differences in children's lives. These results, however, do not generalize to any program called "preschool," which is why today's preschool programs need to measure their own effectiveness in achieving intended outcomes as part of ongoing program improvement.

Another early childhood program that has been extensively studied is Head Start, the federally funded comprehensive program designed to promote the health and development of 3- and 4-year-olds. Head Start was created in the 1960s and has been the subject of numerous evaluations over its many years of existence. The findings from these evaluations have been inconsistent with studies finding positive effects for none, some, or even many of the outcomes studied. This is not surprising because just as there is more than one kind of preschool, there has been and continues to be more

than one kind of Head Start classroom. Hundreds of different local agencies all over the country administer Head Start. Procedures such as lengthy performance standards are in place to promote uniformly high-quality programming, but with so many centers and classrooms, variation continues to exist. That variation is going to be associated with varying degrees of program quality and effectiveness. Rather than investigate whether Head Start is effective, a more meaningful question for large-scale programs, such as Head Start, would be “Which local programs are most effective and what are the characteristics of those programs?” The answer to this latter question provides the knowledge to support local programs in moving to higher levels of effectiveness.

Program Improvement: Improving the Effectiveness of Established Programs

There will always be a need for the new and innovative approaches to outcomes for children and families. However, many young children are already participating in early childhood programs in their communities and measuring the effectiveness of these programs is just as important as studying new approaches. All early childhood programs should be interested in setting goals and collecting data to see how well they have achieved them. The message from the efficacy studies in early childhood is that early childhood programs can make a difference; ongoing data on effectiveness is needed to see whether or not a program *is* making a difference this year and every year.

The method for determining effectiveness differs for established, ongoing early childhood programs from the random control design used with a new program. Identifying a group of children to be randomly assigned to not receive a program is not a viable method for collecting the kinds of effectiveness data that programs need for program improvement. Random assignment also is not viable in states or communities with universal preschool, where many young children are already in some kind of program, or for required services

such as preschool special education. Some studies have been able to employ powerful alternative research designs, such as a regression discontinuity design, with programs that meet the requirements for this type of study.

Similar to measuring the effectiveness of an experimental program, measuring the effectiveness of established programs requires articulating the goals the programs are trying to achieve. The programs’ goals need to be framed with regard to outcomes for children and, if the programs also support families, outcomes for families as well. A program for 4-year-olds could have a goal of preparing children to be successful in kindergarten. To operationalize this goal and make it measurable, the program might establish benchmarks for learning across multiple domains that clearly indicate where children should be by the end of the program. Such a goal could read, “90% of the children will score at X level on the Y test of literacy skills” or “90% of the children will be able to identify 20 uppercase letters by the end of the year.” Once a program has articulated a set of measurable outcomes and identified measurement strategies, the program then collects and analyzes the data to see if the outcomes were attained. If the answer is no, the program can identify improvement strategies to increase the likelihood of doing better next year.

Creating benchmarks and measuring outcomes to examine program effectiveness is sometimes misinterpreted as advocating for a highly structured or inappropriate curriculum. Creating goals and implementing procedures to measure attainment of those goals is entirely compatible with developmentally appropriate practice. A closely related misinterpretation is that setting a benchmark for children means using a particular measurement strategy. Goals do not dictate pedagogy nor do they require an inappropriate approach to collecting information on what young children know and can do. Early childhood programs should institute ongoing processes for examining effectiveness and to do that they need to consider using the most valid, reliable, and appropriate measurement strategy for their population.

Accountability: Justifying the Need for Established Programs

Examining the effectiveness of established programs to address accountability questions requires the same methodology used for program improvement, but the stakes attached to the data collected are considerably higher because the program's future funding may depend on the results. Although the potential of high-quality early childhood programs has been firmly established, the use of public funds to support these programs varies across states and localities and remains vulnerable to the prevailing political wind. When policy makers look at test score data for elementary and secondary schools, the effectiveness question is always some variation on "does this school need to improve?" and never "should Grade 4 continue to exist?" At some point, the policy landscape might shift sufficiently so that the effectiveness question for early childhood also is always about how to make programs better. Currently, however, early childhood programs that depend on public funds need credible data on the effectiveness of their programs so they can continue to make the case for why public funding should continue to support their programs.

MEDIA INFLUENCES ON PLAY

Media and technology are playing an ever-increasing role in children's lives. From prescribed media content created by someone else, to sedentary, push-button electronic games and apps, screens and digital activities are having a worrisome impact on active, creative play with all the benefits to social, emotional, intellectual, and physical development that this type of play can provide.

In 2015, the American Academy of Pediatrics reported on a study by Hilda Kabali and colleagues that found one in seven toddlers uses a device at least one hour per day. Today's teachers and parents need to understand how media is changing play in order to acquire strategies that can promote quality play and optimal development in the media age.

The Benefits of Play

For generations, scholars of early childhood education and development, including Jean Piaget and Lev Vygotsky, have recognized play's vital role in children's social, emotional, intellectual, and physical development and learning. While almost all of them agree it is difficult to come up with a simple definition of play, they recognize play as a primary vehicle through which children construct knowledge and skills. Children use play to try new ideas and behaviors in their own unique, hands-on ways. Through play children develop an understanding of their experience, and an understanding of rule-governed behavior, give-and-take social relationships, cooperation, conflict resolution skills, trust, and resiliency. They learn to be, act, and think creatively, and use symbols to represent experience—thereby laying the foundations for more formal academic content later on. Play also helps young children develop the attitudes, values, and skills they need for school success and much more. It's important to realize that no two children's play will ever be exactly the same. In play children are creating their own scripts, building new ideas onto what they already know.

When children use what they know to actively work out new things on their own through play, not only do they learn something new, they also learn "I can do it!" This sense of power and mastery becomes a strong motivator for further play and learning. In other words, the *content*, *nature*, and *quality of the play process* are all essential aspects of play and learning. So when major new factors, such as technology and media, enter children's lives, it is important to figure out what is going on, what it means for children's development and learning, and what we can do to promote high-quality play in the midst of this significant change.

The Problem With Play Today

Less Time to Play

As children spend more time with screens, they have less time to engage in creative, child-centered play. More research is needed to deepen our understanding of the complex impact of reduced playtime

on human development and learning. However, we know enough about the importance of play to assume that playing less can have worrisome implications.

Changes in What Children Play

According to both Piaget and Vygotsky, the *content* children bring to their creative play comes from their experience—what they know, what interests them, what they are struggling to understand. Today, because more of what children see and know, and what confuses and disturbs them too, comes from media, more of their play content naturally contains characters, behavior, and themes that originate from those screens. Nancy Carlsson-Paige and Diane Levin talk about this in their book, *The War Play Dilemma*.

Much of the content children see in the media also goes against the positive lessons adults who care about children would choose to teach them. Instead, program content is often designed to capture children's attention and to sell them products. This can include content such as narrow gender stereotypes and sexualized behavior, violent conflict resolution, and glorification of drugs and alcohol—often presented without realistic consequences and more appropriate for older children. So more and more, children see content intended to create brand loyalty, consumerism, and age compression (children growing up faster because of what they are exposed to), which they then bring to their play and beyond, as Susan Linn discusses extensively in *Consuming Kids*.

Changes in How Children Play and Learn

Teachers report that more and more of children's play seems to reflect someone else's scripts; that their play is not as original or as creative as it was in the past. It is as if they are trying to replicate the appearance, language, and actions of media characters. Often this play involves using highly structured toys that are replicas of items seen on screens, like swords, wands, or spaceships. As Levin discusses in *Beyond Remote-Controlled Childhood*, structured toys keep children's play focused on the

script and allow little room for branching off in new, child-created, and individualized directions. These seemingly “scripted” activities are more like what Piaget called *imitation* than play—it often seems like children are controlled by what they see on the screen, that is, involved in what Levin has called “remote-controlled play.”

Children who primarily participate in remote-controlled play have trouble being active agents of their own play and learning. They have difficulty finding and solving interesting problems through play, a primary motivator for and source of learning through play—that is, they seem to have what Levin has called problem-solving deficit disorder (PSDD). Children with PSDD often say they are bored when they do not have a screen because they have a hard time coming up with engaging things to do on their own. PSDD in play can also contribute to worrisome academic, social, and life consequences because children may not be developing the strong foundations they need for engaging in active problem solving in the learning process.

Changing Social Development

In the past, much of children’s playtime was spent with other children—siblings, neighbors, and classmates. They built a play history together. Each day they picked up where they left off the day before. Older children taught younger children games such as hopscotch, kickball, jump rope, and hand games. As children got older, they took on helping roles with younger children, thereby learning about nurturing and caring in real-life situations. This has been a gradual process and seems to be correlated with the increase in screen time in children’s lives. For instance, Levin reports on interviews of people over 50 years old about their play when they were young, done by her college students in the play course that she teaches. The students found that all of those over 50 who were interviewed remembered playing outdoors without adult supervision. Some, but not all, of the college students played this way themselves too. But almost none of the college students knew children today who played outdoors this way. Now, there has been a radical

decline in this kind of social-relationship-building play. When families are together, siblings often each have their own screens. Few children are outside playing together in neighborhoods; instead, they are inside connected to screens.

With less time to develop ongoing creative play relationships with each other, which play scholars such as Piaget considered vital for optimal social development, we can expect children to have fewer opportunities to develop all the vital social development skills play can provide, such as cooperation and empathy, conflict resolution, and perspective taking. This can undermine a child’s ability to learn how to build caring, connected relationships in the long run. Reports of increasing levels of bullying, teasing, and mean-spirited behavior at younger and younger ages may be related to reduced play. More research is necessary on this issue, but one can ask how the decline of creative play today might be contributing to what Levin has called compassion deficit disorder (CDD).

Less Physical Activity or Nature Play

More screen time means more indoor and sedentary activity from very young ages. This seems to be the case both at home and at school. For instance, a 2015 study of child care centers by Pooja Tandon, Brian Saelens, and Dimitri Christakis revealed highly sedentary environments with screens present, rather than highly active play opportunities. And in a 2012 Policy Statement, the American Academy of Pediatrics voices concern that as children get older there is a trend to allocate more school time toward the teaching of basic academic skills and away from recess and physical play.

In the past, when rural or urban children were not in school, they were outside playing with neighborhood children morning, noon, and night. Children explored neighborhoods and beyond, including nature areas. Being outside meant leaving the media in the house and playing in the neighborhood. Today, many children spend little independent time outdoors and have few opportunities to explore nature in their environments. With fewer children outside, when a child does go outside there may be no one to play with and it can

also feel less safe. Many children today run the risk of developing what Richard Louv in his 2005 book *Last Child in the Woods* called nature deficit disorder (NDD). In fact, it was concern about the physical well-being of today's children that prompted First Lady Michelle Obama to launch her national Let's Move campaign in 2010.

Reclaiming Play

The impact media and technology are having on play make it vitally important that adults help young children engage in rich, creative play over which they have control. Teachers need to be more skilled than ever at facilitating social, emotional, intellectual, and physical development through play. However, the "pushing down" of academic instruction into early childhood settings amid calls for high-stakes testing and teacher accountability is one strong force leading to much less play. It is also diverting teacher education programs away from play-based teacher training and more toward how to teach basic skills as early as possible.

The following are some potential solutions for making sure children growing up today are able to engage in the kind of creative play that leads to optimal social, emotional, and academic learning.

Help early childhood educators become skilled at understanding the connections between media and play as well as skilled facilitators of play. Teacher training programs can influence how teachers facilitate play by requiring the study of play, its role in development and learning, how media and technology influence it, and how to facilitate it in the media age. Teachers need help learning how to create structures, routines, and environments for children that are conducive to high-quality play, within the current academic push-down environment. They need to know how to provide challenges that help children get engaged in problem finding and problem solving in their play rather than imitation of content they have seen on screens.

Teachers also need to be able to help children learn to use open-ended play materials such as blocks and play food and vehicles in play of their

own creation. Finally, it is very important to be able to help children work with the content from media they bring to their play, including about violent and sexualized behavior, which can influence the lessons they learn as they play. Levin spells out extensive strategies for doing this in her books *The War Play Dilemma* and *So Sexy So Soon*.

Make sure early childhood educators understand the relationship between play and academic learning, and how to facilitate the connections between them. Teachers need help integrating the foundations of literacy into play. For instance, talking to children about their play helping to extend it in new ways based on the children's interests, and writing and illustrating stories with children about their play can all help children process their experiences. The better that teachers are able to articulate the role of play in helping establish the foundations for later learning, the better they will be at advocating for play in their classrooms over mandated direct instruction, as well as at explaining how and why screens can undermine play and learning.

Help parents understand the impact of technology on their children's play, why this is a problem, and what they can do about it. It is extremely hard for even the most conscientious parents to fully protect their children from media's onslaught on their children's lives and influence on their play. Educators can respectfully help parents better understand the current situation—what "real" play is, suggestions they can try at home to limit media and promote play, and information on interests their children develop at school that might lead to less media and more creative play at home. Educators can suggest simple toys and household objects that can contribute to quality play at home. Helping parents with these issues requires ongoing attention. The organization Teachers Resisting Unhealthy Children's Entertainment (TRUCE) offers materials and support to share with families.

Encourage more research on changing play. Research has not kept up with the rapid changes in media, play, or the relationships between them. It is vital to learn more specifics about how play is

changing and how these changes are affecting various aspects of children's development and learning. And we also need to learn more about how to effectively manage media in children's lives and to facilitate play in today's environment.

MEN IN EARLY CHILDHOOD EDUCATION

According to the U.S. Bureau of Labor Statistics, as of 2014, 2.8% of preschool teachers in the United States were men, and 19.1% of elementary and middle school teachers in the United States are men. The United Nations Educational, Scientific and Cultural Organization (UNESCO) reports similar gender discrepancies in every developed country. There are three overall reasons to increase the number of men working in early childhood programs: (1) young children, both boys and girls, need and deserve positive interactions with men in their early childhood programs; (2) men who are gifted in working with young children and who would like to make this a career choice should not face barriers in doing so; and (3) increasing the number of men in early childhood programs could encourage more fathers and other male volunteers to become involved in early childhood programs.

All Young Children Need to Interact With Men

On the whole, men and women interact differently with infants and young children. Men tend to be more physical, entertaining, and playful, while women tend to be more nurturing, soothing,

and conversational. It's also generally the case that when young children want to be comforted, they seek out a female caregiver, and when they want to be stimulated and entertained, they seek out a male caregiver. Further, both boys and girls need to be around male and female role models as they grow and develop into healthy men and women.

Women provide young children with a vast array of positive experiences. However, studies have shown that in the classroom most women prefer to engage in art, literacy, and dramatic play activities, while men seem more comfortable with floor activities, movement, rough-and-tumble play, construction challenges, and often more messy environments. These are generalizations, but when the majority of teachers of young children are of one gender, generalizations prevail.

Eliminating Barriers to Men Becoming Teachers

Since the 1960s, women have made gains in choosing professions and occupations. More women are selecting majors in engineering and other hard sciences in college; women are gaining more and higher political positions. Women are, if not breaking the glass ceiling, at least cracking it.

Now is the time to challenge limits to male career choices based on gender stereotypes. In a free society, discrimination of any kind, be it gender, race, ethnicity, income, age, and so on, is unacceptable. And, in a free, democratic, and equitable society, men should be allowed and even encouraged to work with young children.

There are many barriers to increasing the number of men in early childhood programs and elementary schools. These include the following:

- Resistance from some families who believe the societal view that men should not care for or teach young children. This is especially true of some new immigrant families whose culture forbids young girls from being around unrelated men.
- Resistance from many early childhood directors and elementary school principals because they assume parents don't want men in their children's programs.

- A belief that teaching—especially of young children—does not pay enough for male “heads of households.” Yet many single women raising children work as early childhood teachers, despite the low wages that prevail in the field.
- A belief by many in a decision-making capacity that the only reason a man would want to teach young children is to have access to them as potential sexual abuse victims, and thus hiring men opens the program up to unacceptable legal risks.
- A belief by some female teachers that men do not belong in the field, and that the field should remain one of the few occupations that women control.
- A historical view in all societies that women are naturally more capable and able to care for and educate young children.
- Pressure applied to men in the field from other men who do not view caring for and teaching young children as a legitimate occupation for real men, resulting in a lack of support and camaraderie for the few men who do venture into the field.
- A social justice view that presents justice as a struggle of those with power and those without power, and therefore a conflict between men and women. Those who subscribe to this view may not see bringing more men into the field as a priority, because they are focused on raising the status of women.

The solutions to the lack of men in the early childhood field are complex and difficult. Ultimately they require both a societal shift and a radical change within the field itself.

Increasing Male Involvement in Early Childhood Programs

Men tend to be more comfortable around other men; they also enjoy engaging in projects that use their skills and tap into their interests. Projects that are designed to take advantage of these realities can help to increase the involvement of men in early childhood programs and increase their interaction with young children. In one early childhood program, male volunteers designed and built a challenging playground. They enthusiastically

joined in to help with these projects, from scouring the neighborhood for equipment and materials to digging holes for trees and showing off their considerable carpentry skills. Other projects that have involved men include designing and building an elaborate loft and designing and constructing a simple, wooden puppet stage for each of the classrooms in an early childhood program. In another program, introducing woodworking benches and equipment increased the number of male volunteers in the classrooms. While women can and do lead these kinds of projects, men are more likely to generate projects and activities that other men enjoy and in which men will participate. In still another program, fathers, grandfathers, uncles, and boyfriends took over the cooking for an outdoor picnic for all the program’s families.

Conclusion

There is a dearth of male teachers in early education. There are three overall reasons to increase the number of men in early childhood programs: (1) so that both boys and girls can benefit from interacting with men, and observing men and women engaged in healthy interactions; (2) to enable men who wish to care for and educate young children to be able to do so, and (3) to increase the amount of male involvement in early childhood programs. However, a variety of barriers inhibit the ability to increase the number of men in the early childhood field. To address this dilemma, a sincere commitment is needed, both by everyone within the early childhood field and by society in general.

MENTAL HEALTH ASSESSMENTS

Mental health assessments refers to formal assessments used to screen, diagnose, and identify effective interventions for young children at risk or identified with mental health concerns. This entry (a) defines diagnostic criteria used to inform mental health service providers, (b) describes common screening tools used to identify young children at risk for mental health concerns, (c) presents common diagnostic instruments used to inform psychiatric diagnoses of mental health disorders, and (d) discusses assessments to be used when considering intervention approaches for a young child at risk or identified with a mental health concern.

Overview

Identifying young children considered at risk for mental and behavioral health concerns has gained substantial empirical attention over the last three decades. Most research has focused on the efficacy of screening tools and the effectiveness of preventative treatments (e.g., early intervention services) in facilitating healthy social, emotional, and behavioral development for young children. A major challenge in identifying mental health concerns in young children is making the decision to

diagnose a child with a categorical psychiatric disorder or simply identify behaviors of concern that may be a result of a temporary disruption in otherwise typical development.

Both diagnosing and refraining from assigning an official diagnosis while the child develops have advantages and disadvantages. Children who receive a diagnosis are eligible to receive treatments that are prescribed and provided by professionals and, often, billed to insurance or provided at no cost to the family (e.g., early childhood special education). Unfortunately, when a label has been assigned to a child, it can be very stigmatizing.

When parents and/or professionals refrain from assigning a diagnosis, it can become challenging to get the child the intervention services necessary to assist with the behaviors or symptoms that warranted a referral to the professional. The undiagnosed child who displays some mental or behavioral health symptomology and is provided with appropriate interventions and supports may cease to exhibit symptoms within clinically significant diagnostic ranges; the child then no longer warrants a diagnosis and subsequent treatment.

Finally, children are amazingly resilient and many are often very receptive to preventative and early intervention services. However, some children experience trauma, environmental instability, or neurodevelopmental abnormalities that result in mental health concerns that impair their functioning. This entry addresses the journey of the stages of assessment for children who experience “serious deviations from expected cognitive, social, and emotional development” (U.S. Department of Health and Human Services, 1999, p. 123).

Diagnostic Criteria

The fields of psychiatry and psychology have a rich history in debating the nosology and subsequent identification of diagnostic criteria necessary for a person to be diagnosed with a psychiatric disorder. When considering diagnostic criteria and instruments for identifying the young child with possible mental health concerns, both fields recognize the infancy of their respective efforts.

Some of the major debates when considering how to identify the young and developing child include (a) deciphering the difference between categorical diagnostic markers and normalcy, (b) agreeing about how psychiatric disorders are expressed in the developing child, and (c) confirming the utility of current adult diagnostic approaches with the developing child. Developmental psychopathologists have played a major role in assisting the fields in negotiating the relationships between typical behaviors and atypical behaviors in the developing child, as well as providing guidance in adopting a dimensional approach to diagnoses when the categorical approach has failed (i.e., the child displays behavioral inhibitions with persons other than caregivers rather than the child has generalized anxiety disorder).

Psychologists, psychiatrists, and other medical professionals trained in the United States utilize the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) to diagnose and classify mental disorders. After approximately 15 years of substantial debate and revisions, the DSM was updated to its fifth edition (DSM-5). The DSM-5 has been reorganized to highlight age-related aspects of disorders in each of the diagnostic criteria. This new system of organization acknowledges the life span manifestation of symptomology for each disorder instead of designating childhood mental disorders as categorically different. Moreover, the revised system considers the developmental continuum of both the human life span and specific psychopathology. Many professionals refer to the *Diagnostic Classification of Mental Health and Developmental Disorders of Infancy and Early Childhood-Revised* (DC: 0–3R) as a complement to the DSM-5. The DC: 0–3R considers mental disorders within the context of development. Unfortunately, there is little empirical evidence to support the DC: 0–3R.

The Centers for Disease Control and Prevention (CDC) has recently begun monitoring mental disorders among children (i.e., 1994–2011 data published in 2013). Early findings suggest that the most prevalent disorders diagnosed include, in order from most prevalent to least prevalent,

(a) attention-deficit/hyperactivity disorder (6.8%), (b) behavioral or conduct problems (3.5%), (c) anxiety (3%), (d) depression (2.1%), and (e) autism spectrum disorders (1.1%). It should be noted that the aforementioned statistics were based on a population of children ages 3 to 17 years old. The CDC has called for more attention to be given to diagnosis and surveillance of pre-school-age children. Appropriately screening, identifying, and treating mental disorders of young children are emergent fields still in their infancy.

Common Mental Health Screening Tools

Early childhood students with mental health concerns who do not receive effective services and interventions are frequently troubled in their adulthood. These individuals may exhibit unsuccessful, disabling conditions as adults. There is a great need for early screening and identification for children who are at risk or have mental health concerns through assessment instruments, so these students receive the necessary interventions and supports for a more successful future. In addition, federal legislation states that schools are required to provide a free, appropriate public education to early childhood students who are birth to 5 years of age with disabilities. Each school district is required to conduct a multidisciplinary assessment and develop an individualized family service plan (IFSP) for early childhood students with disabilities, including those who are at risk or with mental health concerns.

A vital part of assessing early childhood students who are at risk of mental health concerns is screening. Universal screening for all students is highly recommended. *Universal screening* is defined as systematic screening of all children within a given class, grade or set of grades, school, or district on social-emotional indicators that the school professionals and community have agreed are important. More specifically, mental health screening is defined as the early identification of children at risk for possible mental health disorders that may interfere with expected growth, learning, or development that warrant further assessment, diagnosis, or

evaluation. Various screening tools are used for identifying early childhood students who are at risk or have mental health concerns.

There are numerous screening tools that analyze mental health concerns in early childhood students. The educational professionals have the task of finding the most appropriate instruments for meeting the mental health screening needs of the student. Screening instruments can be completed by parents, educators, mental health professionals, physicians, and students, if applicable. Table 1 shows some potential mental health screening instruments used by educators, parents, and medical professionals.

The implementation of positive behavior interventions and supports (PBIS) has been associated with a decrease in challenging behaviors related to mental health issues. PBIS is an empirically validated framework for supporting student behavior in educational settings. It is a proactive, preventative, and data-driven practice. There are three tiers associated with PBIS: primary, secondary, and tertiary.

Universal screening, or the primary tier of PBIS, helps identify the students who may need more individualized practices related to their mental health concerns in their educational setting. Proactive behavior management practices are promoted including the use of a clear delineation of

positively stated behavioral expectations, a ratio of six to eight positives to one negative adult-student interaction, positive reinforcement, and pre-correction and reminders regarding undesired behaviors. Educators may also facilitate home-school connections related to mental health concerns and progress, daily behavioral monitoring, functional assessment-based behavior support planning, and comprehensive student-centered planning.

Diagnostic Testing

Most children who are universally screened for mental health concerns will show no areas of concern. However, children who demonstrate multiple areas of concern within the screening process or who are referred to professionals by their parents will participate in further diagnostic testing. Diagnostic testing often employs multimethod assessment to obtain information. *Multimethod assessment* simply refers to the use of multiple methods of evaluation and information gathering for the purposes of identifying a child's level of functioning. Interviews, checklists, behavioral observations, and standardized testing are common assessment techniques used in multimethod assessment for the purposes of diagnosing mental disorders within the DSM-5.

Table 1 Common Mental Health Screening Instruments

<i>Name</i>	<i>Explanation</i>	<i>Ages</i>
Ages & Stages Questionnaires: Social-Emotional (ASQ-SE)	Parent-completed tool with focus on child's social and emotional development	0 to 5 years
Behavioral and Emotional Screening System (BESS)	Universal screening tool identifying behavioral and emotional strengths and weaknesses	3 to 18 years
Brief Infant Toddler Social Emotional Assessment (BIT SEA)	Brief, comprehensive screening instrument to evaluate social and emotional behavior	1 to 3 years
Pediatric Symptom Checklist	Brief screening questionnaire used to identify psychosocial problems in children	4 to 18 years
Temperament and Atypical Behavior Scale (TABs)	Screening or assessment tool used to identify concerns in attachment, sensitivity/activity, reactivity, and regulation	11 months to 5 years

As developmental neuroscientists learn more about the developing brain, neuropsychological assessments are becoming a more frequently employed diagnostic tool for children with mental health concerns. *Neuropsychological assessments* are evaluations that seek to identify brain-related deficits and lesions. Some areas assessed with neuropsychological assessments include (a) perceptual and sensory functioning, (b) motor function, (c) verbal and nonverbal functions, and (d) attention and processing ability. A pediatric neurologist may elect to collect additional information using neuroimaging techniques (e.g., magnetic resonance imaging, computerized tomography), but not use the results to make conclusive diagnoses at the time.

A *diagnostic assessment* is a written evaluation conducted by a mental health professional to determine whether a child or youth has a mental health disorder. The mental health professional will often interview the child, family, and school to gather information about the early childhood student's life. After the completion of the battery of assessments,

the mental health professional determines the child's mental health diagnosis, if any. This diagnosis often drives the treatment goals, plans, and services needed for the child. Table 2 delineates potential mental health diagnostic assessments that may be utilized for early childhood students.

Assessments to Inform Intervention Programming

Educators, interventionists, and parents utilize assessments to assist in the development and monitoring of behavioral and mental health programming. The most common assessments used to inform programming typically assess social, emotional, and behavioral development.

Social Skills Assessments

Social skill deficits are a common concern for children identified with behavioral and mental health concerns. Specific areas of difficulty include (a) emotion regulation, (b) self-determination,

Table 2 Mental Health Diagnostic Assessments

<i>Name</i>	<i>Explanation</i>
Behavior Assessment System for Children (BASC)	Assesses adaptive and problem behaviors in children ages 2 to 21 years old
Child Behavior Checklist/1½–5 (CBCL/1½–5)	Widely used, empirically based multi-axial scale completed by parents and caregivers to identify disorders within DSM-5 for children ages 1½–5 years old
Child Health & Development Interactive System	Assesses broadly for mental health symptoms and problems in functioning in children ages birth to 21 years old
Childhood Severity Psychiatric Illness	Assesses severity by eliciting risk factors, emotional symptoms, and functioning problems in children ages 3 to 21 years old
Children's Depression Inventory	Assesses depression (and possibly anxiety and some externalizing problems) in children ages 7 to 17 years old
Conduct Disorder Scale	Rates symptoms in domain of disruptive behavior in children ages 5 to 22 years old
Conners' Ratings Scales	Widely used assessment for assessing inattention and hyperactivity in children ages 6 to 17 years old
Spence Children's Anxiety Scale	Assesses for anxiety in children ages 2½ to 6½ years old

and (c) navigating interpersonal relationships. Educators, parents, and related service providers can utilize social skills assessments to identify specific areas of concern and design social skills programming. The most common form of social skills assessments come in the form of rating scales. Typically, stakeholders in a child's life will respond to a series of questions about the child's social skill performance in several different areas.

Many rating scales are based on the reporter's recollection of previously observed behaviors. However, some scales (e.g., Individual Social Behavior Scale; Play Observation Scale; Assessment, Evaluation, and Programming System [AEPS] Test; Transdisciplinary Play-Based Assessment) include guided direct observations as a part of the assessment. Guided direct observations often include specific behavioral markers for the assessor to look for and document if and how frequently the specific behavioral markers occurred. Other direct measures of prosocial or maladaptive social interactions are often counted by the frequency or duration of their occurrence. Directly observing a child interacting with others in his or her natural environment is the most ideal form of assessing a child's social and interpersonal skills. Finally, data from all stakeholders and direct measures or scales are triangulated and specific social skills are targeted for intervention programming.

Functional Behavior Assessments

Educators are required by federal legislation to implement interventions for students with challenging behaviors (e.g., PBIS), which usually encompasses students who are at risk or identified with mental health concerns. When a student has demonstrated difficulty performing expected behaviors even with guidance (i.e., tier two and/or tier three level PBIS) and/or his or her behaviors impede his or her learning or the learning of others, the school district must complete a functional behavioral assessment (FBA). *FBA* is defined as an assessment process that seeks to explain why (i.e., function) a student displays problematic behaviors in the educational environment. More specifically, the FBA seeks to identify what the student gains or

avoids in his or her environment when he or she uses the problematic behavior.

In order to identify the function of the student's problematic behavior, a battery of indirect and descriptive assessment data is collected. *Indirect assessments* can be defined as any information about the student, behavior, and environment that is not directly observed by the person collecting the data. Common examples of indirect assessments used in FBA include (a) office discipline referrals, (b) interviews with teachers and family members, (c) rating scales, and (d) checklists. Information collected from indirect assessments assists in defining the target behavior (i.e., problematic behavior) and comparing information from multiple sources.

Descriptive assessments are direct observations of problematic behavior. More specifically, when completing a descriptive assessment, the observer will document exactly what happened in the environment prior to the problematic behavior (i.e., antecedent events) and exactly what happened in the environment following the problematic behavior (i.e., consequent events). Anecdotal observation (i.e., ABC recording) and scatterplot analysis are the most commonly used descriptive assessments. The purposes of descriptive assessments are to (a) document the level of the problem behavior, (b) identify setting events, and (c) describe common antecedents and consequences surrounding the problem behavior.

Educators use data from the FBA to develop behavior intervention plans (BIPs). BIPs play an integral role in promoting success for students with mental health issues. BIPs may (a) eliminate the student's problem behavior; (b) teach more appropriate, independent, functional behaviors; and (c) arrange a positive behavior-based environment, which employs appropriate consequences. Table 3 details the steps involved in going from the FBA to the BIP.

Identifying a young child with a mental disorder is a challenging process with grave implications. However, providing early intervention treatment for any mental or behavioral health concern is highly recommended and may require a child to be formally diagnosed. Professionals are encouraged to work closely with families to determine the best

Table 3 Steps From Functional Behavior Assessment to Behavior Intervention Plan

<i>Step</i>	<i>Explanation</i>	<i>Example</i>
1	Through detailed observations and screenings, operationally define the behavior or mental health issue impeding student's learning (problematic behavior).	Jana complains of experiencing a physical ailment during independent seatwork activities.
2	Determine the events that occur before, during, and after the student's problematic behavior.	When the class is given an independent seatwork assignment, Jana raises her hand and tells the teacher of a physical discomfort she is experiencing. Mrs. Bullock sends Jana to the nurse's office.
3	Systematically manipulate the antecedent and consequent events to verify.	First, present Jana with seatwork with a partner and see if she complains of a physical ailment. Next, present Jana with independent seatwork and if she complains of a physical ailment, tell her she is fine and she is to complete her work.
4	Formulate hypotheses about why the student engages in this problematic behavior (i.e., the function of the behavior).	When Jana is presented with independent seatwork, she complains of experiencing a physical ailment in order to avoid independent seatwork.
5	Incorporate the FBA information into the student's behavior intervention plan. Create behavioral goals and objectives that will teach replacement behaviors that serve the same function. Identify supports that will assist Jana in successfully performing the desired behaviors.	Behavioral objective: When Jana is presented with independent seatwork, she will request help from the teacher or a peer in order to complete up to 80% of the daily independent seatwork activities assigned and observed over five consecutive days. The teacher will assign peer tutors for all of the students each week so Jana knows who to approach for assistance.

approach for identifying and determining treatment for each individual child with mental or behavioral health concerns.

MENTAL HEALTH SERVICES

Mental health services refers to the continuum of behavioral health interventions and treatment options for young children with mental and behavioral health concerns. This entry defines and describes the continuum of mental health service options and common treatment approaches to mental health intervention for young children.

Continuum of Mental Health Services

Services for young children identified with mental disorders are limited compared to services for their otherwise disabled same-aged peers (e.g., speech impaired, developmentally delayed). However, when a child has been identified with a mental disorder, a continuum of service-delivery options is considered. Specifically, a team of stakeholders (i.e., professionals and caregivers) consider where, how much, and what types of mental

health services are required for the child to experience therapeutic success. Service-delivery options are considered along a continuum from least restrictive/least intensive to most restrictive/most intensive. It should be noted that the ultimate goal of any child's programming or support team should be to transition a child back to the least restrictive setting that the child is able to successfully navigate. The ultimate goal should be preparing the child to successfully participate and contribute in society.

Home-Based Mental Health Services

The least restrictive/least intensive setting for treatment is outpatient programs. Outpatient programs may be delivered at a professional's office, in a community center, or in the home. For most young children, they will typically first receive community- and/or home-based mental health services. Home-based mental health services are when professionals deliver mental health services in the child's home. One of the major benefits of home-based mental health services for a young child is the professional is able to work with the child in his or her natural environment and everyday routines. An additional benefit of delivering services in the home is the relationship that can be built between the professional and the family. The professional will work closely with the family to (a) identify areas of concern, (b) review how the child is progressing, and (c) teach the family how to assist in working on the treatment goals while the professional is not in the home (e.g., setting up and maintaining a bedtime routine for the child, ignoring problem behavior, guiding a child through a problem-solving strategy).

Children receiving outpatient treatment often receive wraparound services. The wraparound process is a system-level intervention that aims to integrate existing services around the child with mental health concerns and his or her family. Major problems affecting any and all family members are addressed in a comprehensive manner. Service planning is accomplished through "wrapping" individual services and natural supports around the child and his or her family.

Community-Based Mental Health Services

Community-based mental health services may include (a) early childhood mental health consultation, (b) social service providers, and (c) pastoral or church affiliates. It is important for these partners to collaborate with the families and schools while providing services to the young child. In 2014, the Substance Abuse and Mental Health Services Administration and the National Institute of Mental Health announced plans to collaborate with community agencies to raise community awareness and involvement in early intervention in children with mental health concerns. National agencies are providing technical assistance and resources for participating community partners.

School-Based Mental Health Services

Under the Individuals with Disabilities Education Act, schools are required to provide a free and appropriate public education to young children with disabilities. Furthermore, each school district is required to conduct a multidisciplinary assessment provided by a school psychologist or other mental health professional. On completion of a full individual evaluation (i.e., multiple assessments), the multidisciplinary team will design an individualized family service plan (IFSP; specific for families with children ages 0 to 3 with an identified disability) or individualized education program (IEP; specific for students ages 3 to 22).

IFSPs and IEPs are individually designed education plans created by the multidisciplinary team (e.g., educators, community partners, families). Data collected from multiple assessments addressing all domains of functioning are used to determine goals, supports, and services that will promote systematic growth and access to the least restrictive environment. For young children with mental health concerns, many of the goals will focus on emotion regulation and coping strategies, as well as developing adaptive behaviors and social skills.

In many cases, young children with mental health concerns require psychological services to meet mastery criteria on annual goals and/or to access education in the least restrictive environment. When

specialized and/or supplementary services are required, the specific services as well as the amount of time a child is to receive those services (e.g., 30 minutes of direct counseling services per week) are specified in the IFSP or IEP as a related service. Psychological services provided in the school may include (a) counseling services, (b) crisis intervention services, (c) social work services, and (d) therapeutic behavior services. The related service providers work closely with the school, family, and community to promote a positive outcome for young children who may be at risk or with mental health concerns.

Inpatient or Residential Psychiatric Care

Unfortunately, when children are in crises and their caregivers are unable to provide the amount or intensity of supports or supervision necessary for the child's well-being, the child may be admitted to an inpatient psychiatric care facility. It is important to understand that placement in a residential psychiatric care facility is the most intensive and restrictive setting for service delivery. Children referred to residential facilities are typically considered to be "in crisis" and are only expected to remain in full-time, intensive care for a short period of time. Residential psychiatric facilities are the preferred setting for stabilizing children who have attempted suicide, are self-injurious, or have demonstrated the intent to harm people around them. When a child is in a residential placement, it is recommended that professionals and the child's family meet on a frequent basis (e.g., daily or weekly) to review the child's progress and assess the child's ability to be adequately treated in a less restrictive setting (i.e., group home, foster care, or back home with the family).

Common Approaches to Treatment

Approaches to treatment originate in psychological theories: (a) psychodynamic, (b) behavioral, (c) cognitive-behavioral, (d) family systems, and (e) neurobiological. Identifying the appropriate treatment approach for an individual child is best determined by stakeholders involved in the child's

treatment programming. Many treatment plans combine more than one treatment approach for an individual child.

Play Therapy

Play therapy originated in psychodynamic theory. When a child participates in play therapy, he or she is presented with toys and activities and the therapist observes how the child interacts or plays. The therapist may even interact with the child, but he or she is careful not to make any leading or judgmental statements during the interaction (i.e., child-led play). Psychodynamic theory asserts that a child will act out his or her psychological issues when engaging in play. Unfortunately, play therapy has little to no empirical support for its effectiveness.

Applied Behavior Analysis

Applied behavior analysis (ABA) is a well-established approach that is based on behaviorist principles. Behaviorism asserts that an interventionist can only concern himself or herself with a client's behaviors that can be observed and measured in the environment. Moreover, B. F. Skinner introduced the phenomena that behaviors have direct relationships with both the antecedent events (i.e., what happens just before the behavior occurs) and the consequent events (what happens just after the behavior occurs). The therapist will attempt to ascertain a functional relationship between the maladaptive or problem behaviors and the events surrounding them. A functional relationship explains why a person engages in a behavior. It asks the question, "What does the person get or avoid when he or she exhibits this behavior?" Therefore, when a child is receiving ABA services, the therapist will carefully control for antecedent and consequent events that surround a child's maladaptive behavior. More importantly, the ABA therapist will teach more adaptive or desirable behaviors that will allow the child to get his or her wants and needs met.

Cognitive Behavioral Therapy

Cognitive behavioral therapies (CBT) borrow from the major tenets of both cognitive and

behavioral theory. The CBT approach uses the behavioral approach in that it considers the events that surround behaviors, but it also addresses the private thoughts (i.e., cognitions) that accompany the maladaptive behaviors. CBT assumes thoughts and behaviors are related. When using CBT, the therapist must know about and consider the private thoughts of the client when in a therapy session. There are several different types of CBT: (a) cognitive modeling, (b) self-instruction, (c) cognitive restructuring, and (d) cognitive problem solving. All of the aforementioned CBT approaches work to train the client to (a) become more aware of his or her thoughts, (b) consider how those thoughts will affect his or her behaviors, and (b) make more informed behavioral choices.

Family Systems Therapies

Originating in family systems theory, family systems therapies function with the assumption that a child's emotional and behavioral concerns are symptomatic of issues that exist within the larger family system. Therefore, therapists using this approach often will not provide therapy to the child unless the entire family commits to participating in the therapeutic process. Once all family members have committed to the process, the therapist often works with (a) each member individually, (b) different dyads within the family, and (c) the entire family as a whole group. Family systems therapists often employ several different intervention approaches when servicing the family. The ultimate goal in family systems therapy is to assist the family in identifying unhealthy patterns of communication and behavior that exacerbate a child's emotional or behavioral problems, and teach the family how to engage in more positive and healthy activities and interactions.

Psychopharmacological Therapy

Psychopharmacological therapies are the newest approach to treating mental disorders in young children and are based in neurobiological theories. On its website, the National Institute of Mental Health discusses psychopharmacological therapeutic

options, which include behavioral/psychosocial intervention, medication, or a combination of both. Although medication does not cure mental disorders, evidence is beginning to emerge that demonstrates promise in decreasing the symptomology that may impair a child's functioning. Due to the lack of evidence and the possible developmental consequences, many physicians have grave concerns about prescribing medication to young children (i.e., under the age of 10). Many medical professionals recommend families consider other approaches prior to psychopharmacological interventions. It is important to understand that medication may be successful for one child and may not work for another. Finally, children taking any kind of medication for mental health concerns should be monitored frequently by a psychiatrist.

Conclusion

Designing and delivering effective mental health services to young children is an emerging area that is gaining national attention and funding. Children from minority and lower socioeconomic status families often go unidentified and untreated for mental health concerns. Children and families who have an identified need for mental health services are often at the mercy of the professionals they consult. Ethically, professionals must clearly communicate their expertise with families, as well as the rights of the child and family while in the professional's care. Treatment programs should be individualized and sensitive to a family's culture and values.

MENTORS

One possible origin of the concept of *mentor* is the *Odyssey*, where it is discussed in terms of the role an older person might play in relation to a protégé. However, the relationship between mentors and protégés can be understood differently across circumstances and contexts. Correspondingly, mentoring roles have been conceptualized differently in different professions and types of organizations. Nevertheless, with few exceptions, in the field of education, a mentor is typically understood to refer to an experienced teacher in the same subject area who helps new teachers adjust to the teaching

environment and supports them to succeed in the profession, especially during the early years of their career.

Demands on Mentoring New Teachers

Major changes in teacher education include high demands of quality education and professional development. The significance of professional mentoring for the sake of quality education has been highlighted in connection to highly qualified teachers as there has been increasing awareness that the quality of early childhood education programs is related to teachers' qualifications and professional dispositions, such as teaching efficacy, passion, motivations, interpersonal skills, and so forth.

In order to remedy long-lasting problems in the field of early childhood education such as recruitment, attrition, and retention, various mentoring and induction programs have been developed across the states. Within the field of early childhood education, a mentor's responsibilities and mentoring programs differ by school district and state.

There are discrete concepts, definitions, and functions of mentors and mentoring. There are ambiguities and complexities in defining mentoring and the role of mentoring in interpersonal growth and professional development among mentors and protégés alike.

Nature (or Definition) of Mentoring

Despite the lack of consensus in defining mentoring, there are commonalities in understanding mentoring. First, mentoring reflects a unique interpersonal relationship between individuals. Second, mentoring relates to the acquisition of knowledge and skills to be gained or strengthened in an early childhood education environment where protégés are situated. Third, although the mentoring process seems to be linear, mentoring is a dynamic and reciprocal process, producing new roles and expectations between mentors and protégés. In other words, mentoring is transformative in its impacts on relationships and expectations.

The variations in defining mentoring often cause discrepancies in perceptions and expectations

among mentors and protégés. In the school system, mentoring is perceived as a means of teacher development through *one-on-one interpersonal support* and *the evaluation of professional growth and dispositions*.

Mentoring involves emotional support provided by mentors to new teachers, enabling them to succeed in the teaching profession. The trusting interpersonal relationship provides new teachers a way to develop a sense of community in the school setting and allows for them to facilitate use of available resources for instruction as well as to learn school policies within a relatively short period of time.

Mentoring is more than "a peer relationship" between a more experienced teacher and a new teacher within the same area of teaching. Mentoring should produce mutual benefits for both mentors and new teachers through empowering each to enhance professional skills and dispositions required for teaching diverse students and meeting all stakeholders' needs. In order for this function to succeed, mentors need continuing professional development and a desire to devote themselves to self-development. Flexible time and reduced workload should be ensured for the mentor development program so that mentors can be fully equipped with professional skills and dispositions to perform desired functions of mentoring beyond a peer relationship. Mentoring programs are intended to function differently from induction programs and other types of short pragmatic adaptation programs.

Mentoring is more than a supervising process to support and evaluate a new teacher. Power imbalance in mentoring relationships may cause problems that lead to deterioration of new teachers' professional experiences. Mentoring protégés are distinguished by the function of formal evaluation or assistance from a director, supporter, supervisor, guider, advisor, proctor, and evaluator.

Mentoring Today in Early Childhood Education

One critical role of mentors is to help new teachers build organizational and political knowledge

to expand their insights beyond their teaching venue, the classroom. As educational needs change dynamically, contemporary mentor roles need to be reconceptualized.

Mentors and new teachers alike face challenges in meeting diverse children's needs, collaborating with diverse colleagues, and making do with scant instructional resources to meet all stakeholders' expectations and needs. Baron (2006) demonstrated that a mentor should act as "an agent of change and induction as the lever" who impacts the system of the school by his or her own ongoing/continuing professional development and by empowering novice teachers to promote equitable practices. In order to make this possible, critical reflection skills are required in order for a mentor to produce a secure and comfortable basis for professional dialogue, enabling a protégé to be culturally sensitive and responsive to changes in expectations and needs.

Conclusion

Mentoring ultimately helps to improve school effectiveness by preventing behavior problems, reducing dropout rates, enhancing school performance, promoting self-identify, and supporting future career development. However, the practical application of mentoring remains unclear and needs to be reconceptualized.

Due to the reality shock caused by the gap between theory and practice experienced by new teachers, early childhood teachers show a low level of job satisfaction and a high turnover rate. A well-structured mentoring program will help to solve the teacher shortage in early childhood education by supporting and empowering new teachers to remain in the teaching profession. Time-specific and multilevel supportive efforts will ensure successful mentoring for both mentors and protégés and ultimately ensure high-quality teaching with positive impacts on children's learning, and meeting current educational standards.

MIGRANT FAMILIES

Migrant families represent one of the most industrious yet undereducated populations in the United States, making the education of children and families of migrant workers a critical issue. Migrant workers in the United States consist primarily of seasonal workers in fields such as agriculture, fishing, forestry, and plant nurseries. Frequently moving from one job to another as the seasons change and work becomes available, these families often work long hours, under dangerous conditions, and receive very little pay, often making well below the poverty line. According to the National Center for Farmworker Health, children of migrant workers face some of the highest rates of poverty and malnutrition, have the least access to health care, and are one of the most economically disadvantaged groups of children in this country.

Children of migrant workers frequently work alongside their parents, often engaging in strenuous labor for long periods of time, which can have serious negative consequences for both their health and their education. Compared to non-migrating

students, migrating students are more likely to miss or arrive late at school, sleep during class, study for fewer hours, sleep less, and suffer from minor illnesses more frequently. These factors, combined with high rates of mobility and cultural and social isolation, further increase these children's risk for academic failure. For English language learners (ELLs), these risks are often magnified, as they must face additional challenges associated with language barriers. Research on ELL students in the United States has consistently shown that these children are at an increased risk for poor academic outcomes, highlighting the importance of strategies for ameliorating these risk factors. While the barriers to educational success for migrant children are high, particularly for ELL migrant students, research has shown that access to a well-integrated community support system, including access to high-quality early childhood education with support for ELL learners, can help attenuate these educational obstacles and promote positive outcomes for these children.

Because many migrant families speak languages other than English at home, effective bilingual and English as a second language (ESL) programs are a key factor in the academic success of migrant children and families. In a study of Spanish-speaking migrant families, ELL children scored lower than their peers from other backgrounds on all factors related to educational enrichment in the home, including access to books in the home and parental reading. In a qualitative study of rural migrant communities, researchers found that lack of access to bilingual materials, teachers' inability to communicate with parents (particularly with respect to a student's academic needs), and limited parental engagement exacerbated the separation between home and school, thus inhibiting children's academic success. Findings such as these have raised concerns about how to effectively support students who primarily speak a language other than English.

In an attempt to address this concern, Janet Elizabeth Pierce Clark (2011) qualitatively examined educational practices that fostered school and home connections for migrant ELL families and improved children's academic success. After

conducting extensive interviews with migrant parents of children attending "successful" schools (a school where more than 80% of children passed state-mandated criterion tests in reading and math), Clark discovered several themes. Specifically, warmly embracing the children's unique backgrounds, honoring and respecting the families' funds of knowledge (maintaining a strength-based view of migrant families rather than a deficit view), and providing a rigorous curriculum along with support for language learning were found to be salient for parental engagement and student success. Moreover, when teachers provided culturally responsive teaching (involving students in the co-construction of knowledge by immersing them in activities that have personal meaning for them), the result was "a more expansive and dynamic education for children" (p. 455).

The importance of ESL programs for positive academic outcomes has been substantiated in a number of studies of children from migrant families. Research has also shown that targeting at-risk ELL children early on may be a key factor in improving their literacy performance. In a recent longitudinal study of Spanish-English bilingual children from socioeconomically disadvantaged migrant families, Carla Wood Jackson and colleagues found that the ELL students' predicted standard score on an English receptive vocabulary test at kindergarten was nearly two standard deviations below the mean for monolingual peers. While significant growth in the ELL students' receptive vocabulary was observed between preschool and second grade, ELL students' average scores remained below the standard score mean for age-matched monolingual peers. However, initial Spanish receptive vocabulary was a significant predictor of growth in English receptive vocabulary, suggesting that children who show higher initial Spanish performance may have a better propensity for learning new words rapidly. Thus, the researchers suggested that initial language performance in a child's first language at school entry might be a useful predictor of which children may require more intensive explicit instructional support for English vocabulary growth.

The effectiveness of the Migrant Even Start programs has been documented in a number of studies. In a longitudinal study examining a rural Midwestern Migrant Even Start family literacy program, Lisa St. Clair and Barbara Jackson found that family participation in this project was relatively high, with families participating in over half of the offered sessions on average. By the end of first grade, children from families participating in the parent involvement training program scored significantly higher on language measures than the control group. Moreover, in a 6-year follow-up study, the researchers found that children in the treatment group scored significantly higher on statewide reading assessments than children in the control group, suggesting that equipping migrant families with the ability to nurture their children's language skills leads to positive and lasting language outcomes for their children.

As the number of migrant families in the United States continues to increase, the question for many in education is how best to enable students of all backgrounds and ethnicities to succeed academically. Migrant families face many unique and substantial challenges. Factors such as long work hours, high mobility, language barriers, and poor socioeconomics often inhibit these families from becoming engaged with their children's school, placing these children at an increased risk for poor academic outcomes. While many of these factors are beyond a school's control, there is much that can be done to improve migrant children's academic success. By respecting each family's unique culture, fostering parental involvement, and providing high-quality early childhood education with support for English language learners, positive student outcomes can be achieved and the condition of migrant families can be improved.

MILITARY CHILD DEVELOPMENT CENTERS

Almost 2 million children in the United States have one or both parents serving in the United

States Army, Navy, Air Force, Marine Corps, Coast Guard, Guard and Reserve, and Joint Services, and receive care in military facilities housing programs for young children (birth to 5), school-agers (5 to 12 years), and teens (13 to 18 years). Others may be cared for in quality family child care homes on or off installations or attend facilities off-post. About 37% of those children are age 5 and younger and often receive care in what has been referred to as the best child care system in the world: a U.S. military child development center. These 900 centers are overseen by the Military Child Development Program, operated by the U.S. Department of Defense. This entry examines the U.S. military child care system, and particularly the U.S. military child development centers that are operated worldwide.

U.S. Military Child Care System

The Department of Defense (DoD) realizes that caring for the children of U.S. military personnel is paramount in providing for service members' well-being and readiness to serve in the U.S. military. Whether families are present both stateside and abroad on military installations or service members serve in the absence of their families, quality care for their children is crucial. As of late, the U.S. military child care system has become widely regarded as a model to be followed by the rest of the nation.

Since 1989, the Military Child Care Act (MCCA) has become a catalyst for change in the nation's military child care system. High-quality services, standards of quality, frequent inspections, and state licensing and national accreditations have become common for military child development centers. Specialists provide training for care providers and assist in the implementation of developmentally appropriate curricula that mandate best practices in caring for young children. In addition, there are ongoing projects to partner with child care centers "outside the gate" of military installations in order to alleviate the shortage of quality child care openings and to enhance the success of a military family's quest for affordable and quality

child care. The demand for military child care far outnumbers the supply as more than 200,000 children receive daily care, but there are about 40,000 more military children waiting for care.

Standards of Quality and Best Practices in Military Child Development Centers

Child development centers for military children are defined as on-installation child care centers certified, inspected, and operated by the DoD and the specific military branch family services divisions. Each branch maintains its own standards of quality and services, but all are subject to the Department of Defense guidelines for military child care. Approximately 95% are National Association for the Education of Young Children (NAEYC) accredited at all times, with the other 5% incurring reaccreditation or engaging in initial self-studies for accreditation. Child development centers provide full-day, part-day, and hourly care for children ages 6 weeks to 4 years. Military child development centers provide care for military and DoD civilian children. Additional youth programs serve children from kindergarten through the teen years. Most child development centers have wait lists due to the nominal cost (based on a sliding fee scale) and the convenience of the child development center if families are living on installation; however, they often continue to choose military child development centers due to high quality of care and the low care-provider-to-child ratios. In addition, priority is given to active-duty service members and civilian personnel who are parenting singly. Child development centers on military installations offer full-time, part-time, and drop-in care (based on availability) as well as extended care on nights and weekends on some installations. All centers operate under the same health and safety, staff qualifications, and curriculum guidelines although the curricular programs may differ slightly among military branches, installations, program directors, and locations. For example, a child development center in Anchorage, Alaska, or Okinawa, Japan, may have a slightly different

curriculum than a center in Abilene, Texas; Vicenza, Italy; or Honolulu, Hawaii.

The United States Military Child Development Program is a valuable resource for military families as they rely on quality child care as a vital part of their everyday lives. The support that they receive from the Department of Defense is necessary as they endure frequent deployments, temporary active-duty assignments, standing duty, and unpredictable work schedules involving training and long hours. Best practices and high standards in child care for these Americans is not a luxury, but a necessity.

Certification, Licensing, and Accreditation: Standards That Govern Child Care on U.S. Military Installations

The Department of Defense maintains its own certification of child care programs. These are very akin to an individual state licensing process, but, unlike state licensures that vary from state to state, the DoD's certification process maintains consistent standards that are applied to U.S. military installation child development centers worldwide. Military parents (and staff) are able to relocate from one installation to another and enjoy the continuity of care and curriculum from center to center. According to U.S. Military Onesource, the DoD standards not only address the routine health and safety issues found in child care centers, but they also address parent involvement, staff training, and developmentally appropriate practice (NAEYC).

Accreditation by a national accrediting body is mandatory for all child development centers operated by the U.S. government. After completing an assessment of the child development center via a self-study, documents are submitted to the accrediting organization for review, prior to an accreditation visit. Once adjustments are made, accreditation standards must be maintained and are reviewed regularly.

Child care providers working in U.S. military child development centers are required to have higher levels of education and training, and most caregivers receive higher pay than many nonmilitary

providers in states within the United States—resulting in fewer turnovers and more continuity of care for military children. Extensive training by curriculum specialists is required for all providers at military child development centers and extensive background checks are required. Higher pay has been linked to higher quality of care in research studies. While approximately 97% of centers on military installations have earned the status of national accreditation, only 8% to 10% of nonmilitary centers are accredited.

Focus on Social, Cognitive, Physical, and Emotional Domains of Children's Development

Care for infants, toddlers, and preschoolers begins with a knowledge of child growth and development at particular ages and stages throughout the child's life. Best practices in caring for the unique ages of children is of highest importance for care providers as they will be responsible for providing activities and experiences that will enhance and support all domains of growth in the young children in their care. A caring and nurturing environment provides optimum support, whether military children are enrolled in full-time, part-time, or drop-in care. Their need for continued social, cognitive, physical, and emotional growth is at the forefront of curriculum planning, based on the ages and stages of each child individually as well as within a larger group. For example, toddler care will differ from infant care as toddlers are beginning to participate in group-time activities and purposeful and meaningful play, while infants are being held while fed and participating in individual developmentally appropriate activities. Preschoolers engage in activities provided by the Creative Curriculum for Preschool program that supports each child's interest as well as his or her strengths. This project-based early childhood curriculum was designed to prepare care providers with the skills to foster development in each individual child through the use of small- and large-group activities. Targeting the whole child (physical, emotional, social, cognition, and language) rather than specific or even limited

domains of development, this curriculum uses 11 interest areas in order to organize the classroom. Child assessments are an integral part of the Creative Curriculum, where care providers can use observations to plan activities and organize portfolios on each child. Parents are a vital component of the curriculum as providers work with parents in order to provide smooth transitions from home to school and school to home. As it has its roots in research, this comprehensive curriculum is a tool for care providers to plan and implement a content-rich, diverse, and developmentally appropriate experience for young children in military families.

In addition, some preschoolers in military families participate in Strong Beginnings, a program designed to facilitate the transition from home to school that includes school readiness activities in the areas of math, social and emotional development, and literacy/language. These areas provide rich content that focuses on children's curiosity and engagement in learning, positive interaction with others, and development of early and emergent reading skills. Music and movement as well as drama and dance provide opportunities for creativity. The Strong Beginnings standards have been aligned with standards in the Creative Curriculum for Preschool with commonalities in activities and approaches to learning.

Children with special needs (differently abled) are protected under the Americans with Disabilities Act (ADA) and are included in military child development centers. Reasonable accommodations are made to enable children who are differently abled to enjoy the same quality care that other children have. Unless a child's presence poses a direct threat or alteration to the program that cannot be sustained, he or she will be included. Several branches of the U.S. military have implemented programs such as SNAP (Army Special Needs Accommodation Process) in order to determine the best, safest, and least restrictive placement for children who have special needs and whose families have chosen for them to participate in child care activities, and/or sports and fitness activities. The Marine Corps and Navy also have review teams or boards to assist in this process to ensure

that all children are protected under the rights for services as indicated by the federal government.

What Can Be Learned From Improvement of U.S. Military Child Development Centers

Due to the acclaim given to U.S. military child care and its child development centers worldwide during the last two decades, it is imperative that lessons learned from its growth and experience be used to improve the quality of civilian care for our nation's children. As a frontrunner in child care practices, military child development centers have come a long way and are now a model for civilian child care. Child Care Aware of America (formerly NACCRRRA) provided initiatives to ascertain whether civilian care could become a parallel entity to military child care if certain strategies were used. NACCRRRA purports that the reauthorization of the federal Child Care and Development Block Grant (CCDBG) can become a catalyst for improving civilian child care, just as the Military Child Care Act of 1989 did for military child care. Highlights of military child development centers in contrast to civilian centers include consistency across the military branches regarding policies and procedures, subsidies and federal funds for seeking optimal standards of quality, and required extensive background checks for providers. Additionally, parents are consistently involved and are made aware of the true meaning of high quality, and providers are given support to meet higher standards through professional development that leads to higher pay. Most importantly, all military child development centers have or are seeking national accreditation with guidelines based on research and best practices in caring for children. Safe environments for their children with caring professionals have become standard expectations for active military men and women.

MILITARY FAMILIES, CHILDREN IN

Almost 2 million children in the United States have one or both parents serving in the U.S. military. Many of those children (about 37%) are age 5 and younger and are often considered as serving right along with their parents during deployment or active duty, sustainment beyond the first month of active duty, and reintegration or reunion once the parent returns from deployment. Younger children are the most likely to be affected by the challenges of being in a military family. Providing quality care for enlisted family members has a direct impact on the children within those families and those efforts have a lasting effect on the well-being of military children. This entry explores ways in which resilience theory is related to practice in working with

and caring for military children and what we can learn from military children and their families.

Resilience Theory and Practice

Resilience theory has been identified as a workable framework for describing the adaptations of children in military families, especially the impact that prolonged separation has on the resiliency or ability of young children to *bounce back*. Learning to cope during times of duress or stress is pivotal in military children remaining buoyant or being able to “stay afloat.” Their ability to recover well during these adverse times is a sign of the ability to adapt and change, sometimes referred to as remaining “upright” or centered. Not all young children will react the same way to similar stressors, and some may even cope well in spite of the challenges that military life brings.

One resiliency model has been described as a balance scale on which one side of the scale holds risk or stressors in a pan and the other side holds protective factors. Either side will tip, depending on the life event, but the main focus will be to assist young children in remaining centered or in preparing them to rebound or return to center.

Potential risk factors for military children may include fear of loss, child abuse, family violence, frequent relocation, parental stress, exposure to parents with posttraumatic stress disorder (PTSD), and child neglect. In a perfect world, these risks would have been eliminated but in the real world these have long been identified as barriers to the well-being, security, and comfort of young children in military families.

A growing number of researchers are focusing on strengths-based research where there are potential protective tools or factors for young military children that promote success. These may include the provision of at least one warm and caring surrogate caregiver during loss and/or separation from parents, community support for young children after a parent's death or injury, the provision of model child care facilities, and strong family (especially parental) relationships. In addition, to ameliorate or thwart stress, growing evidence

supports that teachers and caregivers of young children must provide additional strategies in order to provide best practices and curriculum in appropriate environments in formal classrooms and child care centers during the absence of military parents. Examples include using open-ended questions to stimulate thinking and fulfill curiosity, providing simple choices to engage the child in decision making, and providing opportunities for using initiative and problem solving. Applying resilience theory to practice has immense benefits for children in military families but also can benefit children who are in civilian families.

What We Can Learn From Military Children and Families

Resilience theory is important as a tool for examining the life course of children in military families, but young children in families outside the military face similar circumstances of separation and loss. Much can be learned from the research that is being done with military families and young children in particular, as there are numerous parallels between young children in military families and in civilian families and there is far-reaching potential for this research to help all children. Events such as separation by death, divorce, incarceration, and prolonged travel for jobs, to name a few, are common for children both inside and outside military families. In addition, nonmilitary children face events such as family violence, child abuse, homelessness, bullying, neglect, and adoption that can become risk factors.

Healthy parents protect the well-being of their children. Parental health is a strong protective factor and predictor of resilience in children, whether in or out of military families. Pathways to resilience also include the myriad of other influences on military children such as neighborhoods, friends, schools and child care centers on and off post, family members from afar, as well as the military itself. These pathways must lead to communities of care that include all of the strengths they have to offer. As military families often remain invisible to those outside the military, it is imperative that any stigma

attached to being military families or any other reasons that prevent military children from getting the care that they deserve be addressed at the local, state, and national (even international) levels.

Reinforcing Their Islands of Competence

Robert Brooks created the term *islands of competence* to describe the strengths that each child possesses and the need to focus on how children use those to strengthen their esteem and buoyancy when experiencing challenges, frustration, and even failure. The islands are the things that children do well or have mastered, enjoy doing, or choose to do when given the opportunity based on past positive experiences. For military children, these accomplishments can be the same as those for civilian children and can foster resilience with each new success. The key for parents, teachers, and caregivers in using their islands of competence is to recognize what those are and provide additional experiences for children to continue to build their self-esteem, which in turn builds resilience.

MINDFULNESS

Mindfulness is a state of consciousness involving paying attention to whatever is happening in the present moment with a curious, nonjudgmental attitude. The term mindfulness can refer to both a temporary state of mind and an enduring personal trait or disposition. While research suggests that some people may be naturally more mindful than others, it also suggests that over time, and with practice, one's state of mindfulness becomes consistently more accessible and more trait-like. This entry offers an overview of mindful awareness practices (MAPs), which have been adapted for teachers and children and introduced in educational settings with the aim of supporting the development of self-regulation. In addition, this entry highlights major research findings on mindfulness-based interventions, including Jon Kabat-Zinn's Mindfulness-Based Stress Reduction program and Lisa Flook's Kindness Curriculum.

Overview

MAPs typically involve directing and maintaining one's attention on a target, such as the breath, and can be practiced both formally (e.g., sitting meditation) and informally (bringing mindful awareness to an activity, interpersonal interactions, or sensory experience in the midst of daily life). MAPs entail monitoring one's experience, moment to moment, in a nonjudgmental way, rather than dwelling on the past or concerns about the future. Typically the attention wanders from the target and the practice involves noticing this, and bringing the attention back to the target, again and again during the practice session. MAPs involve three basic processes: establishing intention, focusing attention, and adjusting one's attitude.

The two basic forms of formal sitting meditation practices are referred to as *focused attention* and *open monitoring*. Focused attention involves focusing attention on a specific target, typically the breath. Open monitoring involves freely monitoring the content of one's experience with

an attitude of curiosity and nonjudgment from one moment to the next.

Research

For over 25 years, researchers have studied the effects of mindfulness-based interventions (MBIs). The most widely researched MBI is Mindfulness-Based Stress Reduction (MBSR), developed by Kabat-Zinn. Numerous studies involving adults have demonstrated that MBSR reduces stress, promotes well-being, promotes adaptive psychological functioning, and enhances attentional skills and emotion regulation. One study demonstrated that MBSR promotes brain structure changes associated with improvements in learning and memory processes and emotion regulation. In several studies involving teachers, Patricia Jennings, Robert Roeser, and Flook have found that MAPs can reduce teacher stress and may enhance their teaching performance.

While MAPs have been applied to promote similar effects among children in educational settings, the research on these programs is in its early stages. Adaptations of MAPs for children lead to questions regarding the developmentally appropriate scope and sequence of such practices, given that children experience dramatic changes in cognition and emotion during early childhood. MAPs adapted for young children in educational settings take a variety of forms, including mindful awareness directed toward sensory experience (such as listening and tasting), guided imagery, generating feelings of empathy and compassion, engaging in discovery of nature, the arts, and physical activities such as tai chi or yoga, or various forms of sitting meditation practices. Typically these practices involve interactions with peers and a teacher who may emphasize personal development and values. In this way, MAPs may feature a worldview including prosocial values.

Most research involving children has been conducted with older children or adolescents. However, a few studies of younger children have shown promise. Flook and her colleagues conducted a randomized controlled trial to explore

whether the InnerKids Program improved executive functioning among second- and third-grade children. The 8-week school-based curriculum includes brief MAPs focused on the breath and movement. Children who had especially low scores on parent- and teacher-reported behaviors demonstrating executive function showed significant improvement. However, the teachers and parents were aware of the children's group assignment so the data are not objective.

Flook and her colleagues developed another MAP designed for young children called the Kindness Curriculum (KC), aimed at cultivating attention and emotion regulation. The preschool version of KC involves mindfulness and kindness practices and incorporates children's literature, music, and movement. Flook and her colleagues conducted a randomized controlled trial of the curriculum in a preschool setting with 68 children. Children assigned to the KC group received two 20- to 30-minute lessons per week over 12 weeks. The study showed that KC improved social competence and report card grades in the domains of learning, health, and social-emotional development. In contrast, the control group exhibited increased selfish behavior. This study also showed that children who scored lower on social competence and executive functioning demonstrated larger gains in social competence, compared to controls. While the measures of selfish behavior involved a task performed under objective experimental conditions, the children's social competence and grades were reported by the teachers who were aware of the children's group assignment, and were, therefore, not objective.

Although there is limited research on the effects of MAPs adapted for use with children in educational settings, the results of this research are promising. They demonstrate that these approaches are feasible and call for further research that is more rigorous and involves larger samples of children.

MODELS

Contemporary early childhood education models began to emerge in the late 19th century, reflecting changing beliefs regarding views of the whole child. Predecessors to contemporary models appeared throughout the 1800s. Johann Heinrich Pestalozzi started designing schools based on the development of the whole child and Jean-Jacques Rousseau's romantic view of the child. The "father" of kindergarten, German educator Friedrich Froebel, based his schools on play and active engagement. Elizabeth Palmer Peabody and Susan Blow introduced Froebel's concept of kindergarten to the United States in the late 19th century.

Psychology emerged as an academic field in the late 19th century and early 20th century, specifically developmental psychology with the work of G. Stanley Hall, Arnold Gesell, Jean Piaget, John Dewey, and Lev Vygotsky. These early developmental psychologists investigated the development of children. Simultaneous to developmental psychology research, education models for the young child began to emerge. From the beginning, early childhood education models incorporated developmental psychology. This relationship continues into the current period of early education. This entry details several prominent models of early childhood education: Montessori education, the project approach, developmental interaction, the Waldorf approach, the Reggio Emilia approach, and the HighScope model.

Montessori Education

Maria Montessori (1870–1952) was the first female doctor to graduate from the University of Rome. After becoming a physician, she worked with children committed to a mental asylum. It was in this time period she began observing children, leading to the development of her education model. Montessori noted that children naturally became absorbed in challenging tasks, and child behaviors became problematic when the children were not challenged. In 1907 Montessori opened her first school, *Casa dei Bambini*.

Montessori education is based on what she termed the *absorbent mind*: the idea that young children learn on their own initiative through sensory experiences and purposeful work. Montessori believed that a prepared environment was critical to successful learning. Her education model includes four distinct periods of growth: (1) birth to 6, (2) 6 to 12, (3) 12 to 18, and (4) 18 to 24. Much of her work focused on the first period of growth, during which the child passes through sensitive periods when she is open to leaps in learning.

Project Approach

The history of the project approach can be traced back to progressive educator John Dewey's work

at the laboratory school in the University of Chicago at the turn of the 20th century. For Dewey, projects were based on inquiry and the scientific method as children engaged in deep exploration. Learning occurred through authentic exploration, based on the child's interest. The project approach encountered periods of uneven popularity throughout the 20th century.

In early childhood education today, project work reflects the influence of Dewey and his student Kilpatrick. Project work consists of three phases: (1) planning, (2) investigating, and (3) the culminating work. The planning phase includes selecting the topic and creating topic and teacher webs in preparation for phase 2. Phase 2, investigating, is the fieldwork from which child-created artifacts emerge. Phase 3 allows children to present the project work through a culminating event. As the children progress through the three phases, there are four interrelated learning goals. These four learning goals (knowledge, skills, dispositions, and feelings) broadly embody the learning occurring through the project work. Project work is often used together with more traditional formal instructional methods.

Developmental Interaction Approach (Bank Street)

The developmental interaction approach is rooted in the educational approach of Lucy Sprague Mitchell (1878–1967), one of the Bank Street College of Education founders. She was a progressive involved in working toward a more democratic and egalitarian society. Mitchell was influenced by Dewey's philosophy and work on how to support children's learning.

The developmental interaction approach is based on developmental theory, including the works of Anna Freud, Erik Erikson, and Jean Piaget. The social experience within the democratic community is emphasized. Play-based learning is used extensively in the curriculum as children explore the social and physical environment. Social studies are the core of the model, and opportunities for children to experience democratic living are central.

The Waldorf Approach

The Waldorf approach was created by Rudolf Steiner (1861–1925) and is based on the philosophy of anthroposophy. Anthroposophy emphasizes humanism and spirituality. In anthroposophy, all individuals are one with the world while searching for their own truth. Childhood is divided into three stages that are similar to those of Piaget. Early childhood occurs from birth to 7 years, middle childhood occurs from 7 to 14 years, and adolescence occurs from 14 to 21 years.

The Waldorf model is based on the whole child, and children develop academically, artistically, and practically. Children learn through imitating their environments, using experiential and sensory experiences that occur during free play and outdoors. Oral language is the major tool used to teach language, often through fairytales told by the teachers. Simplicity is emphasized in all learning, and “academic” instruction is not used in the Waldorf approach.

Reggio Emilia Approach

Reggio Emilia emerged after World War II in northern Italy. Loris Malaguzzi is identified as the main contributor to the curricular philosophy that is based on the belief that children are capable and competent partners in the education process. The Reggio Emilia model incorporates exploration and discovery in a self-guided process.

Reggio Emilia does not use a curriculum, but rather a philosophy as children actively construct knowledge. Children learn through the “hundred languages of children” during long-term projects. The hundred languages refer to Malaguzzi’s belief that children learn through multiple ways of communication. Reggio Emilia programs have a strong community base of support. Parents are considered partners and collaborators, and teachers are co-learners and collaborators. The environment is the third teacher in the child’s exploration and learning.

HighScope Model

The HighScope Perry Preschool originated in Ypsilanti, Michigan, in the early 1960s. HighScope was one of the first early intervention model schools. HighScope incorporates developmental and cognitive psychology, including the work of Piaget, Dewey, and Vygotsky. The children served in these schools range from preschool through the elementary grades.

The HighScope model incorporates several critical components: (a) active learning by the child, (b) a learning environment divided into interest areas, (c) a daily routine, and (d) a plan–do–review sequence of learning. A child’s progress is followed through the use of key developmental indicators. HighScope has a well-developed system of observation and assessment called the Child Observation Record (COR). A significant amount of longitudinal research has been accumulated indicating the success of the Perry Preschool in educating children from high-risk environments.

MONTESSORI PROGRAMS AND ENVIRONMENTS

In Rome in 1907, Maria Montessori established *Casa dei Bambini*, the Children's House, in collaboration with a building project supported by the banks of Italy. Casa dei Bambini included the children from lower-income families, from ages 2.5 to 7, in the San Lorenzo district. This multistory apartment building housed the original Casa dei Bambini with an enclosed courtyard for outdoor experiences. The families living within this poverty-stricken area of Rome were encouraged to enroll their children in Montessori's school. Young children with disabilities were welcomed and included in the school population because Montessori believed that all children had a capacity to learn. At the Centenary of the Montessori Movement conference in 2007, the Bank of Italy opened its Montessori Preschool for tours. The collaboration between Montessori's approach and the banks of Italy has continued into present day.

Montessori developed a curriculum reinforced by the natural development of children, observations of the children in their environments, and the individuality of each child. She believed that every child had potential that was waiting to be revealed. Activities within the classroom required the children to utilize their five senses in this hands-on approach. Montessori believed that children were more successful when they were left to work with materials independently, in their own control, at their own pace.

Finding children working for extended lengths of time is not unusual in the Montessori classroom. Their work is respected and concentration protected. Montessori promoted the idea of the absorbent mind of children. She established prepared environments for children to interact with carefully prepared materials, after an introduction by the teacher, at their own pace and in their own space. She described seeing the children absorbing a variety of aspects of reading, writing, mathematics,

botany, zoology, and geography without getting tired. She understood the learning environment to be essential, and she was the first to have child-sized tables and chairs. The environment was to be appropriate for the children's sizes, encouraging interaction at each child's own pace and in his or her own time.

The Role of Teacher as Guide

In the research on learning and creativity, it is clear that the processes of creative thought require freedom and flexibility on the part of the teacher. Rather than employing memorization and regurgitation of information, children should have ample opportunities to explore and examine phenomena closely on their own. It is also important for children to be able to work out their own mistakes in the time needed to do so without interruption.

Montessori encouraged her teachers to guide their students. Teachers who serve as guides recognize the sensitivity needed to carefully facilitate the children's process of exploration. Children are invited to pursue directions in thought or interesting problems to solve with positive support from their teachers. This enables children to work toward the exploration and experimentation of their own ideas, their own mistakes, their own solutions, and their own new interpretations to experiences and the manipulation of materials.

Prepared Materials and Organized Environment

Montessori designed prepared materials that were child friendly, strategically designed, and often self-correcting in nature. As she worked with children, studying her results regularly, Montessori developed a variety of materials for the curriculum areas of practical life, including self-care, science including the natural world, literacy, music, mathematics, and geography. Montessori's school included areas in which these materials would be carefully and thoughtfully organized and displayed. Montessori believed children had sensitive

periods of learning that would be especially amenable to certain types of learning experiences, and she wanted to be sure that they could work during these times in a thoughtfully prepared and organized environment. Montessori also recognized that children were more productive when given the opportunity to come out from behind desks and tables, and pursue learning with materials in their own spaces, often on a rug on the floor, undisturbed for as long as they were involved in the activity.

An example of a carefully designed material is the “pink tower.” The tower consisted of graduated square wooden blocks that fit inside one another. The task, as introduced by the teacher, requires the child to start by laying out all the blocks in order of their size. The child would then choose the largest block to serve as the bottom of the tower. The child would then use visual observation and tactile information by using a finger to trace the perimeter of each increasingly smaller block to determine which one was the next largest and should be stacked on top of the previous block. The child successfully completed the pink tower when all blocks were stacked on top of one another with the properly sequenced sizes in order, one on top of another. The blocks were all painted pink to eliminate a visual distraction from the child’s determination of differences in size of blocks.

The pink tower was carefully prepared for the child’s use and was self-correcting in that if the child put the sizes in incorrect order the tower would not be stable. Once the introduction was given, the child would be encouraged to work, in uninterrupted time and space, to accomplish this task and correcting his or her own mistakes along the way in a trial-and-error fashion.

Another example of a classic prepared material is the set of graduated cylinders. These wooden cylinders were carved out of a rectangular block of wood and set in graduated sizes, from the smallest to the largest diameter. They were designed with little handles on top so the child could easily pull out each cylinder. Once the teacher introduced the activity, the child would be encouraged to pull out all of the cylinders and line them up according to

Figure 1 The Pink Tower

Source: Rebecca George.

increasing diameter next to their wooden block “home.” Then the child would use visual and tactile information by observing each block and using a finger to trace the circular diameter of that block. The child would then decide which hole was the home to this block in the long wooden rectangular base. These wooden cylinders and their wooden base home were all the same natural wood color so color would not be a confounding characteristic as the child was solving this task. Again, the child is encouraged to take the time and space needed to complete this activity. The materials are self-correcting in that if the child doesn’t put them in the correct order, there will be one or more cylinders that are left outside their home. Montessori fostered the idea that the child should be free to work on projects without being rushed or interrupted and solve the task in his or her own time.

Careful Observation

The processes of learning and creativity employ a careful use of observation. Astute observation is the elemental process for gathering sensory input that can later be processed and developed in creative

Figure 2 The Graduated Cylinders

Source: Rebecca George.

modes of application. Montessori expressed the importance of supporting opportunities for observation and gathering sensory data in the learning processes of the child.

When the teacher helps direct the student's development of careful observation, creative exploration is facilitated and strengthened. Montessori recognized that the child becomes an active observer of the world and increasingly recognizes fine distinctions and variations across elements in the concrete world. These repeated experiences with observation, comparison, judgment, and decision making are what Montessori believed built intelligence and furthered development.

Mathematical Learning

Montessori developed a sensory-rich approach to understanding mathematical concepts. She created counting beads on wires, from one to flats of 100. As the child counted the beads, with each number starting out a different color to demark differing amounts, the child could add numbers together by physically counting the beads on wires and linking them together. Quantity and place value are naturally encountered; as the numbers increase in amount, the child is encouraged to build physical models of each number. Montessori built these mathematical materials ensuring a sensory link to the evolving concepts

of number and number processes involving mathematical thinking. When Joy Faini Saab visited the Bank of Italy Montessori School in 2007, a 5-year-old student easily built a physical model for a self-chosen number (3,654) using beads on wires and flats of 100 beads, laid in a cube to become a stack of 1,000, along with the standard number labels. This emulated the Montessori approach of incorporating child-initiated learning, problem solving, sensory input, observation, tactile experiences, and individual initiative.

Problem Solving

Creative problem solving requires experiences and flexibility, and manipulation of materials in fluid and manageable ways. Recombining materials and ideas allows the child to solve problems in unique methods.

Montessori encouraged sensitivity on the part of the teacher. The teacher who is sensitive to the inherent curiosity of young children supports problem solving. The child is encouraged to be the problem solver in all experiential tasks, thereby encouraging children's industry and initiative in creative tasks. Self-efficacy is supported by success at real tasks. Montessori observed this and encouraged teachers to provide opportunities for students to encounter tasks in their own time and at their own pace, free to try and try again if needed.

Figure 3 The Counting Beads

Source: Rebecca George.

Fostering an Atmosphere of Initiative and Industry

The creative learning process flourishes in an atmosphere of initiative and industry. When children are supported in the business of learning, they are more likely to engage in challenging tasks requiring initiative, industry, problem solving, and creative thought.

In Montessori's approach, children are supported in their meaning making without interference. They have uninterrupted time to discover, attend, observe, compare, contrast, and classify phenomena. In this way, creative learning processes of the mind, forming a rich content foundation of understanding and sensory knowledge of concepts, are facilitated.

Focus on Sensory Information

In the learning and creative thinking process, sensory information must be gathered in as many modes as possible. Once the phenomena have been studied, through the senses, ideas can be processed and combined in new ways of thinking.

Montessori acknowledged the power of sensory exploration. She encouraged the children to use all sensory modes of exploration as they manipulated materials and recombined elements of sensory play. Montessori helped other adults realize that children must employ their senses in creating understandings of their world. Her observations of institutionalized children with mental disabilities yielded this belief. Montessori documented her observations and analyzed them, resulting in the development of her sensory-rich approach to teaching all young children.

Fostering an Atmosphere of Psychologically Safe Experimentation

In the learning and creative thinking process, an atmosphere of psychologically safe experimentation is paramount to success in finding new ideas. Once the student is assured of a safe environment in which to suggest new ideas, without the fear of embarrassment or ridicule, learning and creativity are fostered.

Montessori encouraged this psychologically safe environment for trial and error to take place. She supported an atmosphere in which children could try out new ideas without being chided or ridiculed. Their trial and error could employ revision without the negative effects of failure found in more traditional settings. Montessori advocated the possibility for the child to experience failure at a task and then an ample opportunity for that child to stay with the task to be successful.

Movement Is Encouraged

Learning and creativity often employ various types of intelligence. Children who are bodily kinesthetic in nature process their understandings through movement. Montessori's observations had revealed that children depended on their physical involvement with new phenomena.

Montessori honored the child's physicality by encouraging the gathering of information and the processing of ideas through touching, moving, and experiencing. She was one of the first leading educators to identify the importance of movement in the learning processes of children. She helped others see the difference between fidgeting and sensory input. A child in a Montessori classroom is free to arrange for involvement in a task in a time and place that is conducive to a full sensory interaction with the materials at his or her own pace.

Music Is a Learning Opportunity

Montessori advocated the inclusion of music in the curriculum. She restated this desire in her publication of her advanced methods book describing the importance of musical education during the sensitive period of ages 3 to 6 years as a foundation for building musical skills and appreciation for the future. Child-sized instruments and movement to music was a regular part of her method. Montessori recognized the importance of children demonstrating their response to the rhythms and melodies of music through marching, playing, notating, and responding to live and recorded music.

Encouraging the Richness of Process Over Product

Intelligence, development, and creative thought are all direct results of the processes of exploration, manipulation, and recombination. When children are immersed in rich experiences that they control, they are more likely to engage creativity. Once creative endeavors are successful and flourishing, the child's self-efficacy is enhanced.

Montessori expressed that the aim of education is not an external one; for example, it is *not* the object that the child should learn how to place cylinders in order by size. Rather, Montessori described the goal of education as an internal one. She believed the child should have ample opportunities to develop the ability to observe, to make careful comparisons, to reason, to form judgments, to decide and thus, by repeating these experiences as often as needed, intelligence and true development will result. Inherent in this goal is the desire for industry and exploration in the daily experiences of the child. Montessori encouraged trust and respect in adult interactions with children. This is the very rich basis, the fertile ground from which learning and creativity can bloom and flourish.

In conclusion, Montessori was an astute observer of young children. She saw the process of the development of intelligence and creative thought reveal itself in children's manipulation of the environment and their creative recombining of phenomena. Montessori created a method of teaching young children that incorporated a carefully planned environment filled with intriguing materials for children to experiment with in their own trial-and-error processes in their own time. When given the inspiration, opportunity, support, and materials, children's learning, creative thinking, intelligence, and problem solving can thrive. Montessori's work has stood the test of time and has been validated throughout history as a valued, effective, honored, and respectful approach to encouraging the learning, development, and creativity of young children.

MORAL DEVELOPMENT

Moral development refers to the emergence and progression of an individual's sense of right and wrong across his or her life span. Moral development theories focus on various dimensions of morality—describing age-related change in understanding and adherence to philosophical principles, moral emotions, care for others, and the degree to which one's behaviors conform to societal norms and expectations. These theories are also concerned with issues of what might account

for change and the factors that impact on development. This entry offers an overview of early research on the moral development of children by key thinkers in the field, including Sigmund Freud, Lawrence Kohlberg, and Jean Piaget, and further considers contemporary perspectives on the topic.

Moral Development: Early Research

Early scholars were concerned with the question of how children become functioning and “moral” members of society. Although approaching this issue from divergent perspectives, a common underlying thread was the idea that moral development was a process whereby children’s behaviors and motivations were initially externally controlled and later internalized.

Freud suggested that infants and young children start as egocentric beings focused solely on fulfilling their desires and needs; but through socialization, they learn to balance desires with societal norms and values. In his psychoanalytic work, he suggested that underlying this development was a complex process of identifying with socialization agents and learning to repress desires or transforming them into socially accepted behaviors. Behavioral and social learning theorists presented a contrasting view by emphasizing the consequences of actions. Although they were similarly concerned with age-related change, they pointed to external agents’ punishment or rewards for behaviors as accounting for the development of children’s socially accepted and moral behaviors.

For the better part of the 20th century, scholarship on moral development was dominated by cognitive development theory and a focus on how thinking and reasoning about right and wrong evolve with age. Perhaps the most prominent theorist within this field was Kohlberg, who proposed a stage theory of moral development that depicts the individual as having an increasingly complex understanding of and adherence to justice-oriented principles. Kohlberg expanded on the original theory proposed by Swiss psychologist Piaget that depicted moral development in two stages—heteronomous morality (i.e., inflexible

rules, right and wrong is based on consequences) and autonomous moral reasoning (i.e., guilt is based on intentions and rules are based on mutually agreed-upon social contracts).

In his expansion of the theory, Kohlberg proposed three levels that subsumed six stages of moral reasoning. In Level 1, pre-conventional morality, individuals are not yet reasoning based on society’s rules or norms. Most common in early childhood, individuals at this stage make judgments in an egocentric manner in order to avoid punishment and/or obey authority (i.e., Stage 1, punishment-obedience) or to maximize gains for one’s self or others (i.e., Stage 2, instrumental relativism). In Level 2, conventional morality, individuals are keenly aware of and internalize society’s rules and norms and make judgments based on what might be seen most favorably by others (i.e., Stage 3, good boy/girl orientation) or make judgments regarding right and wrong based on laws, duty, and obligation to authority (i.e., Stage 4, law and order). Individuals within Stage 4 tend to see rules as inflexible and necessary to maintain order—thus, adherence to laws and rules becomes equated with what is right. Finally, in Level 3, post-conventional morality, the individual operates based on principles that underlie laws and conventions rather than their literal interpretation. Within this level, Stage 5, social contract, rules are seen as a mechanism to benefit the greater good. Thus, rules are not fixed and must be changed if they no longer serve the vast majority. In this stage, moral judgments are based on what will benefit the most number of people. Finally, in Stage 6, ethical principles, reasoning is based on abstract moral principles of justice and human rights—which may or may not conform to laws or popular opinion. Ethical principles followed here are important for their own right (e.g., justice) rather than its products.

Several researchers criticized this early scholarship on moral development. For instance, Carol Gilligan suggested that Kohlberg’s depiction of development from self-focused to rights-oriented principles is strongly biased toward males. She argued that although males may indeed be more likely to make decisions based on principles of

fairness and justice, females are more likely to emphasize principles of caring and the protection of relationships. Other researchers have questioned the degree to which moral cognitive theory, premised on Western philosophy, is reflected in other societies, for instance, where Eastern philosophy and religion are more heavily espoused, or where collective and interdependent relationships are valued over independent rights. Indeed, cross-cultural research suggests limitations with regard to the degree to which Kohlberg's proposed stages, and particularly the presence of the highest levels (e.g., Stage 6), can be identified across various societies.

Contemporary Scholarship

Newer conceptualizations of moral development focus on a range of domains and do not necessarily espouse a clear line of progression from purely external to internal control. One example of this conceptualization is Nancy Eisenberg's work on prosocial moral reasoning. She proposed the following levels of moral reasoning in situations where there are no clear laws or guidelines—hedonistic (self-focused), needs-oriented (intending to meet the needs of others), empathic (helping based on emotions evoked by the situation), and internalized/altruistic (judgments based on internalized beliefs and values). The body of work that she and her colleagues have conducted suggests that individuals may shift between levels of moral reasoning depending on various situational demands such as the strength of cues, relationship between actor and potential recipient, as well as a host of individual-level factors (e.g., age, gender, cultural background).

Moreover, although earlier research depicted the first few years of life as a period where there was a lack of internal principles but instead a need for externalized control, contemporary scholarship suggests the presence of many components of moral reasoning, behavior, emotions, and their precursors in early childhood. Soon after birth, for instance, infants appear to display distress at the sound of other infants' cries. Referred to as "emotional contagion," this distress is specific to the

sound of an infant crying versus other noises and sounds, and researchers suggest that this is a precursor to empathic responding. By toddlerhood, children display a host of other-focused behaviors (e.g., offers to help, comforting of others, responding to distress). Indeed, during this time, significant gains are made in emotional skills related to moral development such as empathy (e.g., showing concern when someone else is in distress) and cognitive skill such as perspective taking—both of which are implicated in moral and prosocial development. Moreover, both experimental and field research has documented children's display of helpful behaviors and concern for others that, although rudimentary, suggests the presence of moral and other-focused actions very early on.

Recent works on moral development have also emphasized the importance of early relationships in the formation of children's morality. For example, young children have been found to look to parents' reactions in the face of ambiguous situations (i.e., social referencing). Moreover, parenting practices—the use of inductive strategies (e.g., explaining rules, engaging children in dialogue) versus power assertion (e.g., children must follow because parents hold authority)—and having a close and supportive relationship have been linked to stronger internalization of moral principles.

Finally, the acknowledgment of the role of the child in his or her own socialization is somewhat unique to contemporary research. Early psychoanalytic, learning, and cognitive development theory all emphasized the roles of external socialization agents. Research now suggests the importance of children's own dispositions in their socialization. Components of children's temperament (i.e., early personality traits and dispositions), specifically inhibitory control (i.e., ability to control one's own behaviors), and impulsivity are linked to later conscience development. Moreover, children's characteristics also impact the various external factors noted earlier. For instance, children's dispositions can impact on the quality of the relationship between parent and child. Thus, children are not passive characters in their own moral development but are active participants co-constructing their

own experiences and affecting the very socialization agents once depicted as fully responsible for molding children into moral beings.

Implications

The research on moral development presents several potential implications for strategies that parents and educators can employ in fostering children's moral development. There is a robust body of work that supports the importance of inductive socialization practices over power assertion, for example, as conducive to the development of independent and internalized moral reasoning. Strategies that promote empathy in children also appear to be integral to the development of moral understanding and care for others. This includes such practices as helping children recognize their own emotions, as well as helping children understand the impact of their own behaviors on others. Assigning tasks and chores also appears to foster responsibility and a sense of contribution that is also linked to moral development. Finally, the modeling of positive and moral behaviors (e.g., helping others, donating) by socialization agents (e.g., parents, teachers) appears to be more powerful in fostering these same behaviors in children as compared to talking about or ordering children to do the same.

MORAL DIMENSIONS OF TEACHING

At its core, teaching is an inherently moral endeavor. It is so for two very basic reasons. First, teaching is founded on the relationship between a teacher and a student. Relations are in essence moral in nature; thus, the relational nature of teaching imbues it with moral significance. Second, teaching entails decisions and actions on the teacher's part that influence the growth and well-being of others. Teachers seek to change those in their care for the better, that is, toward desirable ends.

Overview

Because early childhood educators work so intimately with young children and families at significant times in their development, it is crucial that early childhood educators be aware of how their work is infused with moral significance and moral meanings, both for themselves as professionals and for the families and children with whom they work. As moral dilemmas may arise between a teacher's beliefs and values and those of administrators or the children's parents, an

awareness of one's own beliefs and values and how they play out in teaching and curricular decisions can increase understanding of what might cause moral dilemmas to arise and provide guidance on how to resolve them.

Research

One way of understanding the moral dimensions of teaching was outlined by John Dewey when he made an important distinction between ideas *about* morality and *moral* ideas. For Dewey the former are ideas about goodness, honesty, or justice, which provide information but do not change one's character or move one to action. However, it is moral ideas that provide a means by which individuals can improve. This distinction by Dewey makes possible an understanding of teaching as a moral endeavor.

Alan Tom elaborated on this distinction when he proposed viewing teaching as a moral craft. Viewing teaching as a moral craft directly challenged the long-held view that teaching is based on principles provided by research in the behavioral and social sciences. Teaching was seen as the application of guidelines and principles based on scientific research. Tom sought to synthesize the moral aspects of teaching with the craft basis of teaching. Tom combined these two elements to create the moral craft metaphor for teaching. The moral craft metaphor moved the view of teaching beyond a skill-based, technical activity to one that combined a moral vision with reflective, deliberate, and thoughtful action.

Research in the early 1990s saw several groups of researchers continue to explore the moral dimensions of teaching. Seeking to look deeper into the moral aspects of teaching, Philip Jackson, Robert Boostrom, and David Hansen undertook extensive observations in a range of classrooms from elementary to secondary, both public and private. Through this work they uncovered a variety of ways that the moral is infused and present in both formal and informal curriculum, teaching methods, the routines and rituals of the classroom, room arrangements and the displays of students' work, and the ways teachers express themselves to students.

Of this group, Hansen has continued this line of research. Hansen posits that teaching is a moral activity because teachers strive to help others learn what they previously did not know, to acquire skills they did not have, to view the world from perspectives they did not have. Because teachers endeavor to change students in ways that focus on positive and desirable ends, and this calls for teachers to be attentive to the intellectual and moral growth of students, teaching is at its core a moral endeavor.

Cary Buzzelli and Bill Johnston have chosen to look at how the moral is expressed in specific aspects of teaching, such as the ways teachers use language, exercise their authority, and teach about culture. Here consideration is given to how the moral can be found at the critical point between teachers' personal beliefs about teaching and learning and the social realities of the classroom, such as the values of the families who attend the program.

Gary Fenstermacher, Virginia Richardson, and Matthew Sanger approached the moral dimensions of teaching by considering the manner in which a teacher approaches teaching, the nature of the teacher as a person, the nature of the teacher's methods, and the features of the curriculum. The manner of a teacher includes such things as the dispositions a teacher has toward students, for example, whether the teacher expresses honesty, fairness, patience, and openness in relationships with students. These same dispositions are expressed in teaching methods. This approach is similar to Elizabeth Campbell's work, which frames teachers as ethical professionals whose work involves both practical wisdom, the content and pedagogical knowledge of teaching, as well as the professional wisdom to exercise both content and pedagogical knowledge in an ethical manner.

Studies conducted with early childhood educators have focused on the aspects of teaching dilemmas that gave them moral significance. Researchers in Sweden found that early childhood teachers described moral dilemmas as falling into two categories. One set of dilemmas involved conflicts among teachers, colleagues,

and parents over what each believed to be in the best interests of the child. The second set of moral dilemmas involved the tension among teachers' values, the values of their profession, and the society at large. A more recent study with Turkish early childhood educators found similar results.

Implications for Early Childhood Education Teacher Education

Increased attention is being given to teaching about the moral dimensions of teaching in teacher education programs. Teacher education programs have begun to include more experiences through which preservice teachers can develop the abilities to recognize the features of a dilemma that give it moral significance and the strategies to resolve moral dilemmas in ways that respect all involved. Preservice and in-service teachers can benefit from discussions in teacher education programs and with colleagues in professional settings that examine moral dilemmas from multiple viewpoints. Through these activities and practices teacher educators seek to develop in preservice and in-service teachers the knowledge and dispositions that allow them to approach the practice of teaching through a moral framework.

MOTHERS

Although children have meaningful relationships with many people, the relationship between mother and child is unlike any other. Mothers serve in all sorts of roles, including as teachers, mentors, disciplinarians, and confidants. This unique relationship often begins prenatally and is far reaching throughout the life span, impacting both mother and child in many capacities.

The bond between infant and mother is instant. Sensory perception in early life seems to be tuned to recognize caregivers above other individuals, and more specifically, to recognize mothers. An infant's auditory perception is well developed, even before birth. This means that the infant is born knowing what his or her mother sounds like. They are able to recognize and identify their mothers' voices and unique speech patterns. Research has demonstrated that infants seem to have some memory ability of sounds they heard in the womb. This would mean that infants not only recognize their mother almost instantly by voice, but also have a capacity to recall her sounds and the way that she speaks that differentiates her from other adults. In research settings, infants have been shown to have the ability to discriminate between their mother's voice and the voices of others in the first few days of life.

Infants are also able to recognize their mothers by using their sense of smell. Within the first few days of life, an infant knows the scent of his or her mother and can discriminate her smell over other women. While vision is poorly developed at birth, infants begin scanning the edges of their mother's faces during feedings. The distance that an infant is typically held from an adult's face during feeding times is approximately 6 inches, the perfect distance for them to begin to focus their eyes. As they get older, they begin to focus on moving features, such as eyes and mouth. However, early on, just scanning the edges of the face and focusing on the contrasts created by the different features help infants begin to visually recognize their mothers. These early abilities not only play a role in helping the infant determine his or her mother or primary caregiver, but also comfort and provide confidence to the mother when she sees that her infant recognizes her. These interactions lay the foundation for the lasting emotional bond between mother and child.

In early life, infants do not even have the cognitive ability to recognize themselves as an individual. At first they see themselves as an extension of their mother, not really realizing that they are a separate being. As they develop cognitively,

emotionally, and socially, they begin to realize that they are separate with their own thoughts and feelings. Early care-giving interactions between mother and child set the stage for later development. Consistent, warm responses to hunger or distress teach the infant a lot about early relationships. The strong emotional bond between child and primary caregiver, known as attachment, is an invaluable connection that not only influences the outcomes of the child, but also impacts future relationships in which the child plays part.

The attachment relationship, typically between mother and child, plays an integral role in a child's future development. Children actively explore their environment using their mothers as a secure base. Being able to freely explore, while knowing that a caregiver is present, gives the child a feeling of safety and security. Children with secure attachments are generally confident, competent, have high self-esteem, and do well academically. They are also typically well liked by their peers. Children with insecure relationships often have trouble with aggression, and can also be clingy or overly self-reliant. Typically, children with insecure attachments often have trouble socially, academically, and are at higher risk for numerous other negative outcomes.

Mothers are often the child's first teacher. From birth, mothers are teaching their children skills and character-building traits. Just responding warmly and consistently to a child's cues for hunger or distress is teaching the child consistency in expecting an outcome. When a mother talks with an infant during feeding and naturally pauses to gauge a reaction from the child, they are teaching the child rules for later communication and conversation. As a child matures and becomes more active in the relationship, teaching continues through interactions. Labeling objects, pointing out items, and focusing on selected things with children help teach them words and build their vocabulary and teach them rules about how to engage with others socially.

Mothers are also often one of the child's first disciplinarians. Positive guidance techniques used by the mother to redirect or distract children from

harmful things or negative behaviors are typically the first form of guidance used. When a mother uses natural and logical consequences to teach children about the outcomes of behavior, children begin to internalize what behavior is desirable, and why. These important interactions not only are important for the child's behavior but will also lay the foundation for the way a child responds to peers and other adults. Social learning is a crucial part of being human, and mothers are largely responsible for this weighty task.

There is no question that the relationship between the mother and child is unique. Research highlights the many amazing abilities that infants have to recognize their mothers and demonstrates the importance of a strong mother-child relationship on future child outcomes.

older individuals, and at the same time they sometimes appear to be sensitive to things that are beyond everyone else. Yet from birth on, children experience *motivation*.

In order to understand how children experience motivation, it is first necessary to define motivation. The term originates from the Latin, *movere*, which means "to move." While textbook definitions of motivation differ, the term generally refers to the underlying tendencies that move individuals toward specific, goal-related actions. Motivation is an ongoing process that brings purpose to problem solving and serves as the basis for self-regulation. Thus, motivation plays a role in both the initiation of and persistence in goal-related behaviors. The plethora of motivational theories, in part, reflect the multifaceted nature of motivation. Diverse theories also help to explain motivation as it varies from individual to individual and from age to age.

Children are born with a desire to learn and master their environments. This is *mastery motivation*. This general propensity toward learning becomes increasingly domain specific as children grow older. Thus, while many young children attend to just about any new experience, as they get older they are likely to express a love of learning within a specific domain, such as math or science.

The connection of an individual with some domain, or with any part of the environment, represents one important category of motives and motivational theories. In fact, the most common attempt to individuate types of motivation focuses on the source (i.e., external or internal) of motivational factors. Individuals who are *extrinsically motivated* engage in behavior in order to receive external rewards or avoid punishment, while *intrinsically motivated* individuals engage in behavior for internal reasons, such as personal interest. Differentiating between external and internal motivation is extremely important when considering the motivation of young children. As previously stated, young children are intrinsically motivated to master their environments. However, it is not uncommon to witness the extrinsic motivations of children. They may show an eagerness for favorite food, attention, or particular toys.

MOTIVATION

Early childhood is a unique period. Children in the first few years of life seem to be oblivious to many experiences that could not be ignored by

A second approach to motivation focuses on the need for relatedness, competence, or autonomy. *Relatedness* refers to the desire for community and support. *Competence* can be loosely defined as the need to succeed. Even if both of these needs are met, individuals still strive to have control over their own learning, and thus require opportunities to develop and express autonomy. Environments and situations that are structured to meet these basic needs are conducive to the development of intrinsic motivation. That is, when needs are met, individuals are more likely to engage in learning for the sake of learning.

As children develop, their needs fluctuate and change. The need for competency in infants, for instance, may be fulfilled by learning to eat finger-food without help, whereas toddlers may fulfill this need by successfully engaging with a toy without parental guidance. In order to facilitate motivation in children, specific emphasis should be placed on fulfilling their idiosyncratic needs.

Attribution theories may help to explain the motivations of children who have developed self-awareness. The assumption is that, on some level, individuals think about their success or failure. Three factors—*locus of control*, *stability*, and *controllability*—form the basis of attributions. Individuals with internal loci of control attribute the outcome of behavior to internal factors, such as effort, whereas those with an external locus of control tend to attribute outcomes to uncontrollable factors, such as luck. Stability refers to whether children attribute outcomes to fixed or dynamic causes. If causes are seen as fixed, children are probably unmotivated to engage in problem solving. They believe the outcome is unchangeable, despite increased effort.

Beliefs concerning loci of control and stability are highly related to controllability; children are unlikely to be motivated to engage in behavior if they believe they have little control over the outcome. Many attribution theories are directed at adults and used to explain specific behaviors in academic and/or work environments, but clearly there are important implications for

early childhood. Children who believe they have control over the outcome of their behavior, and are encouraged that their efforts can increase success, are more likely to grow confident in educational settings and remain motivated to learn.

Children also develop important expectations about themselves and the impact they may have on the environment. At this age, *expectancy-value* comes into play. The key idea here is that motivation is a function of the expectancies concerning the outcome of the behavior, and the value the individual places on the goal. Thus, if a child expects that success is possible, and highly values a successful outcome, he or she is motivated to strive toward achieving the goal. It is important to note that both positive expectancy and value are necessary for motivation in this model; even if children place extreme value on a positive outcome, they will make no strides toward achieving the goal if they expect success to be impossible. Note the implication for parents working with young children. It is not enough to simply tell children they “have to do something.” This places little value on the behavior, thus doing nothing for the child’s actual motivation. However, when children are encouraged to find personal value in certain actions (i.e., behaving at a restaurant in order to set a good example for a younger sibling), they will more likely remain motivated to engage in the behavior.

Self-beliefs are often included in explanations of motivation, perhaps even as a main ingredient. Children with positive self-efficacy—the belief in one’s own ability to successfully complete specific tasks—are likely to display persistence and view challenges as opportunities for growth. A slightly more general perspective focuses on self-concept. Here the idea is that children form self-beliefs based on external sources, such as interactions with others and cultural/societal norms. Thus, as children interact within a rapidly changing environment, their motivation evolves along with their sense of self. These processes are extremely important for early development. A young child’s sense of self develops as he or she continually interacts with new individuals and accumulates life experiences.

The early years shape self-beliefs, thus impacting the motivation that stimulates and fuels behavior.

Internalizing Mastery Motivation

Mastery motivation was introduced earlier, the premise being that children are born with a desire to understand and control their environments. This mastery motivation forms the basis of intrinsic motivation; if infants and young children are supported in their quest to understand and control their immediate environments, they are likely to internalize these feelings of autonomy and competence and become intrinsically motivated to continue learning as they grow older. Infants and young children exhibit impressive persistence in task-directed behaviors in order to fulfill their needs. Toddlers will remain focused on retrieving a toy from behind a barrier, and revel in a sense of efficacy when they finally succeed. Young children who are appropriately challenged and stimulated will be continually determined to master their environment, thus building the foundation for intrinsic motivation to learn in the later years.

Infants and young children display mastery motivation by demonstrating persistence at somewhat difficult tasks, as well as a preference for control and challenge. As infants recognize that their actions have an effect on the environment (e.g., a baby smiles and her parents respond positively), they begin to develop a sense of competence while simultaneously fulfilling the need for relatedness with the caregiver. As infants progress to toddlerhood, their self-awareness is also rapidly developing. The ability to self-regulate forms the basis for autonomy; young children are able to make simple choices and take pride in “doing things on their own.” They are still inherently motivated to master their environment, although this now involves more intricate processes (e.g., a toddler remains engaged in filling a wagon with blocks).

As children grow, their motivation becomes more differentiated across domains. However, children 5 to 7 years old still typically imply an undifferentiated motivation, which reflects the

“all-or-nothing” attitude common to this age group. It is imperative to provide for the needs of these children and create environments that foster motivation, because they are quick to conclude that they are “good at everything” or “bad at everything” (Harter, 1999). The lack of differentiation in motivation of young children can be attributed to a lack of knowledge of self; in order for children to demonstrate intense motivation toward succeeding in a particular domain, they must have an understanding of who they are, and what they value. Furthermore, young children have not been exposed to as many learning experiences as adolescents, and thus have not had the opportunity to focus on specific domains. Establishing beliefs that foster the development of intrinsic motivation (i.e., encouraging the establishment of internal loci of control by stressing the importance of effort, or modeling how to persevere in the midst of difficult situations) at a young age builds a strong foundation for more specified motivation in the later years.

While it might be tempting to simply categorize motivation as intrinsic or extrinsic, it is unlikely that children engage in activity due to purely intrinsic or extrinsic motives. Indeed, while most would agree that intrinsic motivation is preferred over extrinsic motivation—especially with regard to the expression of creativity—there are several types of extrinsic motivation, which vary in terms of self-determination. *External regulation*, for example, occurs when behavior is purely motivated by the desire to earn a reward or avoid punishment. *Introjected regulation* refers to behaviors that are performed in response to internal pressures, such as guilt or fear of rejection. Thus, while the motivation is internally driven, the child engages in the behavior more out of obligation than internal interest. *Identified regulation* occurs when children identify with the reasons for performing a behavior. When the reasons for performing a behavior are commensurate with individual values and beliefs, regulation becomes integrated.

In this sense, it is possible for children to internally regulate behaviors that were originally performed due to external factors. Young children are

likely to engage in behaviors that please their parents (external motivation), but as they gain experience, they begin to recognize and identify the reasons that their parents support this behavior (identified regulation). If appropriate support is provided, children can then integrate these beliefs into their own values. That is, over time, the behavior can become more intrinsically motivated.

Environments That Stimulate Motivation

Quite a bit of empirical research has been conducted to determine which environments encourage young children to build the belief systems and develop the skills that facilitate intrinsic motivation. Environments that meet the basic needs of relatedness, competence, and autonomy provide necessary stimulation for the development of motivation. Parents and educators who are calm and supportive provide relatedness, creating a safe place for learning. When young children are encouraged to make their own decisions, they develop both a sense of autonomy and competence. Although it is tempting to consistently reward good behavior, it is important to support learning itself, rather than always providing extrinsic rewards. Although external rewards may be associated with immediate learning gains, they are typically countered by decreased levels of motivation for learning; students become motivated by the external reward rather than by learning itself. While praise often fulfills the need for relatedness, generic praises such as “you are so smart” should be used sparingly, as they often lead children to assume that their success is related to a stable trait and thus guaranteed. Educators and parents should provide specific feedback that emphasizes effort and reminds the child that she or he is in control.

As is implied by the multitude and diversity of theories of motivation, there is no “one-size-fits-all” recipe for motivation. Motivation is driven by the unique perceptions of individuals. What one child perceives as controlling, another may perceive as “too open” and unsupportive. One child may see his or her goal as specific and interesting, while another may feel the need to create entirely

new goals. It is thus essential to resist making broad generalizations when describing motivation; it cannot be neatly categorized, but rather must be considered within unique learning and social contexts. Motivation is the underlying force of goal-directed behaviors, and when appropriately supported can help young children develop confidence, an appreciation for both intrinsic and extrinsic motivation, and an appreciation of learning and growth.

MOVEMENT EDUCATION

Movement education is characterized as physical education emphasizing fundamental motor skills and the discovery of variations through concepts such as body and spatial awareness. It encompasses a philosophy that is success oriented, child centered, and noncompetitive. Movement education experiences are most critical in early childhood, as they lay the foundation for all facets of movement tasks, whether they are play, work, creative expression, or any other aspect of life requiring movement. This entry provides an overview of the beginnings of movement education and its differentiation from traditional physical education, a discussion of its benefits to children, and a general explanation of its approach.

Overview

Rudolf Laban is generally considered the father of movement education. A dancer, choreographer, dance educator, and director of modern dance and ballet companies, Laban studied movement in its many forms. But it was not until Adolf Hitler's regime forced Laban to immigrate to England that

his work began to gain recognition. In England, he developed a system of analyzing movement through what he termed the elements of time, weight, space, and flow. He also determined that experimentation should be used as a teaching method, and this is the origin of the problem-solving teaching styles synonymous with movement education. Laban and his associates developed his work in English schools. Gradually, his methods extended to Western Europe and then to the United States, where movement education has had its highs and lows but has continued to evolve.

Although movement education is physical education in that learning takes place primarily through the physical domain, it is not physical education as many adults remember it. That is to say, it is not the subject in which any of the following are true:

- The teacher stands in front of the students and tells them exactly what to do and how to do it. (Jumping jacks and sit-ups may surface in the reader's recollections.)
- There is a right way and a wrong way to do every task.
- Only the physical domain is considered.

Instead, movement education

- often uses less direct and more child-centered approaches to instruction,
- allows children to experience success almost every time, and
- involves the whole child.

Benefits to Young Children

Although it is commonly believed that children automatically acquire motor skills as their bodies develop, maturation only means that they will be able to execute most movement skills at a low performance level. Continuous practice and instruction are required if a child's performance level and movement repertoire are to increase. Once a child is able to creep and walk, gross motor (large muscle) skills should be taught just as other abilities are taught. It is by starting with the basic motor skills and experimenting with their myriad variations that children

become comfortable with and competent in their physical abilities. They will later be able to employ these abilities in many facets of life, both functionally and expressively.

Because movement education relies primarily on problem-solving methods of instruction, this content area also contributes to cognitive and creative development. Further, it requires children to interact with each other in situations so that they must take turns, share space, and collaborate; therefore, movement education additionally contributes to social and emotional development. In these ways and others, movement education contributes to the development of the whole child.

Primary Teaching Method

Exploration should be the teaching method most widely used in movement education experiences. Because it results in a variety of responses to each challenge presented, it is also known as divergent problem solving. For example, a challenge to demonstrate crooked shapes could result in as many different crooked shapes as there are children responding. A challenge to balance on two body parts can result in one child balancing on the feet, another balancing on the knees, and still another—who may be enrolled in a gymnastics program—performing a brief handstand.

To employ exploration, the teacher presents children with a challenge (e.g., “Show me how tall you can be” or “Find three ways to move across the balance beam in a forward direction”), and the children offer their responses in movement. The teacher can then issue additional challenges to continue with and vary the exploration (extending the activity; e.g., “Show me a way that you can do the last challenge with your body closer to the floor”). Alternatively, the teacher can issue follow-up questions and challenges intended to improve or correct what was seen (refining responses; e.g., if the teacher has issued a challenge for the children to make themselves as tall as possible and some children remain flat-footed, the teacher might ask, “Is there a way you can use your feet to make yourselves even taller?”).

The primary tools employed in exploration are the elements of movement: space, shape, time,

force, flow, and rhythm. If we liken movement education to the study of grammar, the skills themselves can be considered verbs, while the elements of movement are the adverbs.

As an example, if the locomotor (traveling) skill of walking was being explored, there would be a number of choices regarding how to perform the walk: forward, back, to the side, or in a circle (here the element of space is being used). In addition, the walk could be performed with arms or head held in various positions (shape), quickly or slowly (time), strongly or lightly (force), with interruptions (flow), or to altering rhythms (rhythm).

Too often in the past, physical education was taught “to the middle.” In other words, teachers chose activities that could be handled by children of average ability. Although the system worked well for these children, students who were not as skilled were constantly lagging behind, resulting in a vicious cycle of failure that eroded their confidence and led to more failure. Highly skilled children, on the other hand, were not sufficiently challenged and became increasingly bored.

Exploration allows every child to participate and to succeed at her or his own level of development and ability. In addition to the self-confidence and poise that continual success brings, this process promotes independence, helps develop patience with oneself and one’s peers, and allows the acceptance of others’ ideas. Perhaps most important for young children, exploration as an instructional method in movement education leads children to discover the richness of possibilities involved in the field of human movement.

MULTIAGE EDUCATION

Multiage education refers to a classroom in which two or more separate age groups or grades are taught in the same setting. In the United States, this phenomenon, which has also been called “combination,” “multigrade,” and “mixed-age” education, was previously the norm, during the times of one-room schoolhouses. Over the years, following various education reforms, the prevalence of, and public opinion of, multiage education has changed. This entry provides an overview of multiage education, including its history, common arguments for and against its use, and the current state of its implementation.

History

In the United States, prior to school reform in the 1800s, multiage classrooms were the norm; children of various ages studied as a whole group or as separate subject groups. As a result of rapid economic growth, extensive immigration, and the common school movement, which caused a proliferation of organized systems of publicly supported schools, the current grade-centered approach to education began in the 1800s. At the same time, innovators in education called for a child-centered approach focused on developmentally appropriate curriculum, which resulted in the current conceptualization of multiage education.

During the 1900s the work of Lev Vygotsky and other developmental scholars emphasized instruction that extended child knowledge (e.g., instruction within a child’s zone of proximal development). The brief reemergence of multiage education in the United States began in the early 1990s and its popularity appears to have peaked by the mid-1990s. A few states, including Kentucky and Michigan, implemented initiatives mandating the availability of multiage classrooms. Additionally, the National Multiage Institute was established in 1995; it offers graduate-level courses in multiage practices for teachers and administrators.

However, the duration of these state initiatives was limited. Kentucky’s reform was modified 6

years after it started; various services discontinued due to lack of funding, and the number of multiage programs in Kentucky has been decreasing since. Michigan followed a similar trajectory with its initiative: Multiage programs abounded then ceased about 6 years later. Nevertheless, scholars have investigated the advantages and disadvantages of multiage education.

Advantages

The multiage model of education’s value is due to its focus on the process approach to learning. Through this approach, educators seek to teach and understand each individual based on his or her developmental trajectory. The teacher presents broad concepts to students, allowing students to work at their own pace and learning level, instead of pushing through a common curriculum without complete mastery.

Many have argued this child-centered method of teaching increases verbal abilities and overall student motivation due to the targeted opportunities for learning. Research has also suggested children learning in classrooms among peers of varying ages also develop cognitively at a faster rate. Additionally, this type of classroom has been used as a valuable alternative for students at risk for retention or those who struggle to meet standardized testing requirements.

In addition to academic gains, multiage classrooms have been shown to enhance children’s social skills and emotion regulation. Due to the emphasis on cross-age learning, students of differing academic and developmental levels collaborate and teach each other, creating an environment of cooperation, flexibility, and higher self-esteem. These classrooms have been seen to enhance tolerance for individual differences and decrease competition. Researchers and teachers of multiage classes have found greater rates of student obedience, school attendance, and overall sense of community.

Challenges

Despite the potential benefits of multiage classrooms, a variety of difficulties with implementation, training, and buy-in have deterred schools from its use. Educators have expressed concern over the

increased workload caused by preparing lessons specific to children's differing needs. Multiage classroom teachers require in-depth training in assessing students' developmental abilities and knowledge, and providing differentiated instruction. In overpopulated urban areas, multiage classrooms may also be difficult to implement due to disproportionate ratios of students to teachers.

Furthermore, due to the introduction of U.S. grade-level standards, school administrators have been less likely to promote multiage programs due to pressure to educate students according to grade-level standardized tests. Students in multiage classrooms, thus, may struggle to produce proficient test results due to their unfamiliarity with particular curriculum standards. This presents collateral issues with school funding, parental satisfaction, promotion, and student grades.

Parents tend to express concern about multiage classroom instruction with frequent worries that their children will not receive appropriate instruction at the appropriate level (i.e., within their zone of proximal development). Many fear that their older children will be overwhelmingly tasked with helping younger peers, or receive inadequate attention. Finally, some researchers have found little to no evidence that these classrooms foster greater academic achievement when compared to homogeneous grade-level groups.

Current Usage

Despite the conflicting views on multiage education, it still has a place in contemporary education, and research continues to investigate its utilities. However, one needs to look beyond the context of the United States to see multiage education in common practice. Multiage classes are widespread in developing and industrialized countries alike. In most cases, multiage classes arise out of economic necessity rather than as a strategic teaching choice. A variety of current sources demonstrate that multiage education is in place in South Africa, Ireland, Hungary, Peru, Nepal, and Pakistan, for example. The main advantage of multiage education in these contexts is that it creates access to education for more children. Unfortunately, many teachers in

these classrooms are not adequately trained in peer teaching techniques. Nevertheless, it does provide an opportunity for more children to participate in education, consistent with a commitment made by participants in the World Education Forum in 2000 and reaffirmed in 2015 with the Incheon Declaration. Coordinated by the United Nations Educational, Scientific and Cultural Organization (UNESCO), the Education 2030 Framework for Action builds on the global Education for All initiative, which aims to provide quality basic education for all children, youth, and adults.

MULTIAGE SPACES

Multiage spaces refers to learning environments that are intentionally designed for groups of children with a range of chronological ages. These include indoor and outdoor areas for learning through play, exploration, and discovery. In multiage spaces, early care and education settings foster children's growth in social, emotional, physical, and intellectual domains within multiage groupings. Programs, schools, or early care and education centers that use multiage groups provide classrooms that are arranged with furniture, materials, and designated areas to focus on meeting children's developmental needs. In recent years, it is less common to see multiage spaces in the elementary school setting. This entry provides an overview of multiage spaces and the purposeful arrangement of space to build on the benefits of multiage groupings, which include continuity of care, integration of curriculum, and social learning.

Overview

Multiage spaces reflect the philosophical stance that children's learning is based on their developmental needs rather than their chronological age. Among children who are the same age, there will be different approaches to learning, different abilities, different interests, and different background knowledge. This requires particular attention to the physical setting and classroom materials to address the unique needs of the learners. Classrooms inspired by Montessori or Reggio Emilia are often characterized as multiage spaces because they are designed for groups of children with a wider span of ages. These incorporate more hands-on learning in smaller groups, with less emphasis on whole-group direct instruction.

Multiage spaces promote social learning among the groups of children. Within the environment, children interact frequently with each other, with the adults, and in small groups. This type of learning environment is arranged to support social interaction, flexible groupings, and peer-to-peer

learning. Rather than traditional desks in rows and segmented use of time and materials, multiage spaces are naturally open and flexible. The space is divided into areas for learning centers, small-group investigations, and consultations with teachers and peers. The focus is on children's developmental needs and age groupings are de-emphasized. Children, spanning a range of ages, work and play together. In a multiage space, they discover and engage with in-depth projects to construct knowledge about the world.

Learning Environments for Multiage Groupings

Infants and Toddlers

Multiage spaces for infants and toddlers allow for smooth transitions between early care and education settings, even within the same facility. Children's development during the first 3 years differs widely. Children reach developmental milestones as individuals. With multiage spaces, it is possible to make decisions based on the needs of the individual child, rather than arbitrary criteria such as a child's birth date. For example, teachers have the flexibility to determine when to move an infant or toddler from one classroom to another. Because the young children spend longer amounts of time in these types of classrooms, the environment is home-like and personalized to the individual children.

In multiage spaces, infants and toddlers have the opportunity to benefit from continuity of care. Continuity of care in a group setting for infants and toddlers occurs when children and care providers stay together for a longer time period, usually the first 3 years. Research has shown the advantages for children to remain with the same adult for a longer period of time. This allows children and caregivers to develop stable, trusting, and consistent relationships.

The learning environments for multiage groups of infants and toddlers have a family-like atmosphere. The comforts and care of a home are combined with experiences that are educational and develop the child's skills and knowledge.

There are different areas to promote movement, soft areas for quiet and calmer activities, and space for personal belongings as well as low, accessible shelves to promote independence. Everyday experiences such as feeding, toileting, and sleeping are arranged with the needs of the different-age children in mind.

The materials within these learning environments for infants and toddlers are not limited for use within a single classroom. The toys, manipulatives, and learning tools can be used throughout a facility as the needs arise. This flexibility in the use of materials is characteristic of multiage spaces. Materials are multidimensional and allow for use in a variety of ways depending on the developmental needs of children.

Health and safety are a primary concern when creating appropriate environments for children who are of different ages and skills, such as mobile toddlers in the same room with infants. Adults must be cautious when selecting materials to ensure that they do not pose any danger, such as a choking hazard. Spaces for groups of the youngest children foster a sense of caring and empathy as the adults and children of different ages play, learn, and interact together.

Preschoolers

Similarly, multiage spaces for preschool-age children accentuate how young children learn. Preschool-age children do not experience the world as segregated into different subject areas. For 3- to 5-year-olds, time, space, and materials are multidimensional. Children learn by making connections to what they already know through play and social interactions. The spaces for multiage groups of preschoolers include a variety of areas for exploration and learning.

Programs such as Head Start often group together children who are ages 3 to 5 years old. Within a Head Start classroom or in any multiage space, the physical arrangement of furniture and materials is focused on how children learn. The use of open spaces and smaller designated areas directs children's learning.

When the curriculum is interdisciplinary and focuses on the development of the whole child, the environment incorporates a variety of opportunities for children to make choices and to construct knowledge. The content of every subject matter is presented and demonstrated in ways that allow for integration. Children are encouraged to interact and manipulate concrete and tangible artifacts, tools, and objects. Children are not confined by rigid rules and expectations for using materials. They learn by the modeling from adults and other children.

This active approach to learning requires spaces that are flexible—to allow for projects that stretch across a table, investigations that occur outdoors, play scenarios that spill from the housekeeping corner into the block area, or in-depth studies with small groups of children who need places to meet and discuss or pore over books. Additionally, in multiage spaces, there is room for play. This means that there is adequate space devoted to accessible storage of props and materials for children to use in imaginative and dramatic play.

Primary Grades

Multiage spaces for children in the primary grades conjure up images of the one-room schoolhouse. Children arrived at the schoolhouse and one teacher managed to provide individualized instruction for a wide range of ages. Often, older students were paired with younger students for guidance and support. Time spent outdoors was as a whole group of children of varying ages. Multiage spaces for school-age children are not as commonplace as they were in the late 20th century.

Contemporary multiage spaces still allow for children's continued learning and development. Just like the preschool learners, children ages 6 to 9 years old rely on active exploration to construct new knowledge by using new experiences to extend and enhance prior knowledge about the world. Within the learning environment, children actively engage with learning centers, hands-on experiences, and projects. The more competent, often older, children serve as mentors to the novice, typically younger, children.

In the primary grades, multiage spaces incorporate learning centers. Learning centers are areas designated for small groups to explore a particular area of study, to use specific materials and to interact with subject matter. Children have access to research materials, technology, and writing tools to independently record their learning. Within a flexible space, the learners can move freely and interact with peers to pursue topics of study.

Role of the Adult in Creating Multiage Spaces

In the multiage space, adults play the critical role of creating a context for learning to happen. The adults arrange the environment, select appropriate materials, allow time for social interaction, and facilitate rich interdisciplinary experiences. All of this preparation occurs with an intentional focus on the individual children and their learning preferences, motivation, and temperament. A main responsibility for the teacher is to be a watchful observer of children and their individual needs. Equipped with knowledge about children's development, the teacher is then able to provide materials to foster growth and to create spaces for exploration of integrated subject matter.

The teacher is responsible for designing spaces that support children's exploration of the physical world as well as foster social interactions. The multiage space is family-like and so all children get to experience being the oldest, youngest, and middle child. The learning environment becomes a safe place to strengthen interpersonal skills of empathy, caring, leadership, and followership. Indoor and outdoor areas are used with multiage groups of learners.

Within each multiage space, adults model encouraging social interactions and facilitate positive and constructive interactions between and among children. Children can observe and participate in resolving real conflicts in the shared quarters. This way, they develop social and emotional skills. Likewise, when there are a limited number of materials available, children have to solve an authentic problem.

An astute teacher is a keen observer of children and intentionally uses the environment to initiate and support these occasions for learning. With careful preparation and guidance from adults, children engage in play, exploration, and discovery. As a watchful observer of children's development and interests, the teacher's role is to prepare the environment to ignite the child's intellectual curiosity.

MULTIPLE INTELLIGENCES

Multiple intelligences theory (MI theory) was developed by Howard Gardner, a professor of cognition and education at Harvard University. Introduced in his 1983 book, *Frames of Mind*, and refined in subsequent writings, Gardner's theory challenges the views of intelligence as measured by the intelligence quotient (more commonly referred to as IQ) and as described by Jean Piaget's universal stages of cognitive development. Arguing that human intelligence is neither a single entity nor a unified set of processes, Gardner maintains that there are several distinct, relatively autonomous intelligences. Individual intellectual profiles reflect varied configurations of these intellectual capacities.

Basic Claims of the Theory

MI theory presents at least three ideas that are revolutionary to our understanding of intelligence: the definition of intelligence, criteria for identifying an intelligence, and identified intelligences. Gardner defines intelligence as a biopsychological potential to process information that can be activated in a cultural setting to solve problems or create products that are of value in a culture. By considering intelligence as a potential, Gardner asserts its emergent and responsive nature, thereby differentiating his theory from IQ, which views human intelligence as fixed and innate. Whether a potential will be activated depends in large part on the values of the culture in which an individual grows up and the learning opportunities available in that culture. Development of the intelligences is influenced simultaneously by individual biological dispositions, environmental factors, education, and personal effort. These activating forces contribute to the expression of a range of intelligences, from culture to culture and from individual to individual.

In the process of developing MI theory, Gardner considered the range of adult end-states valued in diverse cultures around the world, such as computer programmers, teachers, lawyers, athletes,

scientists, and tribe leaders, to name a few. To identify abilities that support these adult roles, he examined empirical data from sources that had not been considered previously for the purpose of defining human intelligence, including brain function, evolutionary history, special human populations, development of symbol systems, and core operations of intelligences. His examination of these sources yielded eight criteria for identifying an intelligence. Of principal importance to Gardner in developing the criteria was capturing the range of purposes and processes entailed in human cognitive functioning. For Gardner, the criteria developed to identify intelligences are the most original and important feature of MI theory.

To date, Gardner has identified eight intelligences: linguistic intelligence, logical-mathematical intelligence, musical intelligence, spatial intelligence, bodily-kinesthetic intelligence, naturalistic intelligence, interpersonal intelligence, and intrapersonal intelligence. Although linguistic and logical-mathematical intelligences have been emphasized in psychometric testing and school settings, no intelligence in the MI framework is seen as inherently more important than the others. Although significantly independent of one another, intelligences do not operate in isolation. Human activity normally reflects the integrated functioning of several intelligences.

MI Theory and Early Education

MI theory can serve as a conceptual framework for implementing developmentally appropriate practice (DAP) in early education. MI theory defines intelligence as a potential; the driving force of DAP is to inspire all children to achieve their highest potentials. MI theory contributes to the implementation of DAP in at least three ways: knowledge of children, curriculum, and teaching and assessment.

Knowledge of children in the MI framework goes beyond describing general cognitive, social, emotional, and physical growth to identify more specific developmental potentials in a range of domains, such as math, arts, science, and music.

Development from MI's perspective is domain specific—young children's intellectual abilities are tied to specific bodies of knowledge and skills, and they are not based on general cognitive structures that operate across domains. Because each intelligence exhibits particular problem-solving features, information-processing capacities, and developmental trajectories, the level of a child's development often varies in different areas. Of critical importance for DAP is to understand each child's intellectual profile—his or her proclivities, strengths, vulnerabilities, and interests—and provide educational experiences that support his or her unique potentials.

With regard to curriculum, MI theory stresses the importance of exposing young children to a wide range of content areas, including literacy, math, and science as well as music, fine arts, performing arts, and movement. Limited exposure decreases possibilities for young children to express themselves with diverse materials and develop their potentials to the greatest extent. It also reduces the likelihood of discovering interests and abilities that parents and teachers can nurture at a young age. An MI-based approach to curriculum invites teachers to use multiple entry points to promote children's in-depth exploration and understanding of topics and concepts essential to early learning and development.

For teaching, MI theory emphasizes building on children's particular strengths and using them to build bridges to other areas of learning. In contrast to traditional approaches that focus primarily on children's deficits, teachers in MI classrooms attend equally to areas in which a child excels. Teachers invite children to participate in learning tasks that further develop their strengths in ways they are motivated to pursue. They also give children opportunities to use their strengths as tools to express what they have learned. Teacher support for children's strengths contributes to a positive self-image and an increased likelihood for success in other learning areas. Effective teaching requires appropriate uses of assessment. To facilitate the identification of children's strengths, a wide range of abilities is sampled in the assessment process.

Since the publication of *Frames of Mind* in 1983, MI theory has become one of the most influential theories in the fields of cognitive psychology and education. It emphasizes the concepts of diversity, equality, possibility, richness, and expansion. It affirms beliefs about children as individuals that many educators hold and practice, and provides them with language to describe children's distinctive intellectual profiles. It calls for mobilizing resources to help individual children reach their highest potentials and to enrich their contributions to society.

MULTIPLE METHODS OF ASSESSMENT

Perhaps more than any other period of development, early childhood relies on a wide range of assessment methods. The use of a specific method is driven by the purpose of the assessment, the availability of assessment tools, and the training demands for the individual completing the assessment. General consensus in early childhood education is that assessments should rely on multiple methods when possible, and that these methods should be used in ways that approach the child in

the most authentic way possible. Multiple methods provide the greatest flexibility to describe this period, while assessing children in naturally occurring environments minimizes the child's test burden (or even awareness), allowing a more valid view of the child. While a full discussion of assessment methods is beyond the scope of this entry, the following discussion does provide an overview of some of the most common assessment methods.

General Methods

The Formal–Informal Continuum

Typically, formal methods are those that are the most intrusive to children while informal methods are less obtrusive, or completely unobtrusive as children may not even be aware they are being assessed. This continuum, while often cited, is potentially misleading, however. Many infer that formal methods are by default more valid and useful, and informal methods lack such characteristics. In truth, any assessment method can yield psychometrically sound results based on how well it is designed and used.

Direct Assessments

Direct assessments specifically engage the child in the assessment process. Standardized testing in schools is the most common example. However, direct assessment in young children differs in substantial ways from this image. First, while older children may be expected to complete a paper-and-pencil test (though this may now be administered via technology) young children are seldom assessed through direct assessment without an adult assessor. In addition, for young children, test materials often include objects for the child and assessor to use in posing and answering items.

Indirect Assessments

Indirect assessments are those where areas of interest are assessed without directly engaging the child. While the child is the focus of the assessment, he or she is not specifically involved in the assessment itself. There are several forms of indirect assessment.

Checklists and Ratings Assessments

Checklists and ratings-based assessments rely on parent or teacher reports of a child's behaviors, skill, and so on. These do not require the child to be under observation or even present during the assessment. As a result, these assessments have no impact on the child, and often can be completed quickly by a range of potentially important reporters of the child's development. These assessments typically (but not always) involve general ratings of children's tendencies or likelihoods of showing certain skills or characteristics. Checklist and rating scales are very similar, and the terms are often-times used interchangeably, although there is a key distinction. Checklist scales usually are marked using a dichotomous scale (e.g., yes/no) while rating scales generally use a scale, typically a Likert scale, to allow for finer scoring on each item.

Observational Assessments

Indirect assessment can also occur through observational assessments. Here, the child is observed and assessed in a naturally occurring or structured setting using a predetermined set of items and scoring criteria. The child's behavior is not specifically guided or elicited as in direct assessment, but the environment may be more or less restricted to highlight the target(s) of the assessment. For example, a child's physical development may be assessed through observational methods when she is on the playground.

Portfolio Assessment or Review

Early educators often develop and maintain portfolios for each child to mark the child's learning and development. While this work is directly obtained from the child, the collection, and subsequent rating of the portfolio, is indirect in that the child is not present. Portfolio assessments are powerful in that they show the child's work, generally in context. However, collecting items and curating them are functions of the early educator, and so reflect the child's learning and development through the teacher's interpretation of how to show it.

Key Differences Between Assessment Types

Regardless of the assessment method, obtaining valid and reliable data requires the use of psychometrically sound tools by assessors who are trained and skilled in their use. Different types of assessment require differing levels of training and experience to administer. Direct assessments of children often require specialized training to obtain the best data. Indirect methods often rely on rating scales that require clear definition for assessors (called raters for these assessments) but often require less formal training. In addition, direct assessments require involvement and time from both the child and the assessor, making them more time intensive than rating scales, which can be completed by the assessor generally with minimal time demand.

A wide range of methods is available for assessing young children. Each presents strengths and limitations, but all must be judged on their psychometric strength and their ability to achieve the purpose for which they are intended. Choice of methods may also be influenced by the language and cultural background of children (and assessors) to ensure they are culturally relevant and maintain psychometric strength when used for diverse populations. Likewise, some methods may be less appropriate for children with disabilities.

MULTIRACIAL FAMILIES

Multiracial families are a growing demographic in American society. These are families where the biological parents come from different racial or ethnic groups. Multiracial children also include adopted children whose biological parents are from two or more races. Some of these families are single-parent families and some grandparents are raising multiracial grandchildren. According to a Pew Research Center study, about 15% of new marriages in the United States in 2010 were between spouses of a different race, more than double that in 1980 (6.7%). Moreover, 35% of Americans claim a member of their immediate family or close relative is currently married to someone of a different race.

Multiracial children are enrolled in early childhood programs throughout the United States. For a variety of reasons, including societal myths and prejudices, and a lack of accurate information about multiracial families and children taught in college preparation programs, early childhood teachers, providers, and experts often lack the knowledge needed to work effectively with families made up of more than one race or ethnicity. Many college multicultural classes and early childhood diversity textbooks do not cover this unique population. This entry describes multiracial children and their families, and provides information and best practices for early childhood programs to work with such families.

Multiracial Families in the United States

There have always been multiracial families in America. In fact, in the country's early history, interracial couples and the children they produced were considered "new Americans" because they

symbolized a rejection of European racism and prejudice. However, European racism soon spread to the New World, and the institutionalization of slavery in America solidified the belief that races should not mix. One result of this ideology was the creation of a pervasive mythology of moral, biological, and intellectual inferiority of mixed-race progeny that still exists today to some extent. In many states, anti-miscegenation laws persisted until the 1967 Supreme Court decision in the case of *Loving v. Virginia*.

The contemporary increase in the number of multiracial families in America began as a result of the civil rights movement. One result of this increase was the creation of an active multiracial moment from the late 1970s to early 1990s. A central goal of the movement was to change the Office of Management and Budget (OMB) process for collecting racial information to enable mixed-race children to choose more than a single-race identity on Head Start, Individuals with Disabilities Education Act, and other school-related forms. Today multiracial families include any combination of the federal OMB categories, such as Hispanic and Native American, Asian and Black, and so on, although African American and White families are still the most obvious and most controversial.

Multiracial Identity Development

A central issue that all multiracial parents must address is the racial identity of their children (unless the family is from a country like Brazil, where mixed-race identity is an accepted norm). Historically, children of a Black parent and a White parent in the United States were expected to identify as Black; other racial and ethnic combinations followed the rule of hypodescent, under which multiracial individuals are expected to identify with the lower-status race. However, today there is a growing belief by researchers, psychologists, and child development experts that multiracial children should embrace their full multiracial identity, and that this developmental process should begin in early childhood. These experts argue that even children whose parents want them

to identify with a single race (usually their minority race) should understand, accept, and embrace their mixed heritage.

Several theorists have studied racial identity development in single-race children. While this differs somewhat, depending on the child's race/ethnicity and physical characteristics, and their social contexts, in general it follows a sequential developmental process, with the child reaching a mature sense of racial/ethnic identity between 9 and 11 years of age. However, for multiracial children, the process is more complex, and more susceptible to contextual cues (for example, a child of more than one race living with a single, White mother or White grandparents, and attending an all-White early childhood program).

In several of the multiracial developmental models, one of the stages involves the child identifying with one of his backgrounds (usually the minority background) and rejecting the other parent's background. When this occurs, the parent who is rejected needs to be understanding and supportive. For multiracial children to progress successfully through each specific stage, they need to have concrete exposure to all parts of the child's background, be given opportunities to explore various conflicts and contradictions, and have hands-on opportunities to explore mixing of colors, textures, sounds, and other constructs. They also need to be around people who continually affirm that being mixed is okay and natural. The goal of this developmental process is to achieve a full, integrated identity, which is usually achieved at the end of elementary school or later.

Teachers working with preschool-age children must fully understand both Jean Piaget's preoperational stage (ages 2 to 7) and Erik Erikson's stages of autonomy versus shame and doubt (ages 1 to 3) and initiative versus guilt (ages 3 to 6) to guide multiracial children through this important developmental process.

Changing Paradigms

To work effectively with multiracial children and their families, early childhood staff need to radically

change their views of diversity, and challenge traditional diversity paradigms and mythologies about multiracial identities. It's no longer White or Black, Asian or Hispanic, brown or blue eyes, curly or straight hair. Race is no longer understood to be determined by a specific, fixed set of physical characteristics. There are no labels or categories; there are traditions, ancestors, combination, values, and dispositions. For the multiracial child the challenge is to be able to (1) integrate all the parts into a whole, including in many cases integrating a minority and majority perspective, and (2) continually respond to uninformed children and adults who make comments to the child such as, "A White man dropped you off in the morning and a Black woman picked you up, so what are you?" In predominantly White programs, multiracial children are viewed as a minority; however, in predominantly minority programs, they also may not fit in.

The Role of Early Childhood Staff

All staff in an early childhood program, including specialists and psychologists, need to find ways to support each multiracial child's healthy identity development, and sensitively follow the guidance of the parents in this process. Because physical cues are so important during the preoperational stage (2 to 7 years old), young children notice physical differences: skin color, hair color and texture, and eye color and shape. Thus young children are naturally aware of physical differences. Early childhood staff therefore need to proactively address issues of racial and ethnic diversity in their program, including multiracial children.

Because young children often struggle to resolve conflicts, follow rules, and function prosocially, issues of race, ethnicity, and identity may come up in conflicts between them. Thus teachers and professional staff need to respond sensitively and supportively.

Unfortunately, the current approach to diversity in early childhood programs reinforces a single-race approach: books about Asians, Blacks, and Hispanics; doll sets where both parents and all the

children look the same; and some multicultural activities that require children to "match" their phenotype with that of their parents. Thus early childhood programs must (1) continually challenge the single-race approach to diversity that is pervasive and normative in these programs and (2) challenge their own views of the racial and ethnic diversity of American families and children.

Specific Ideas for Working With Multiracial Children and Their Families

Multiracial children are like all children, and therefore most advice for working with them is the same as for working with other children. However, they do have unique needs that must be sensitively and supportively met. Some additional ideas include the following:

- Give multiracial children a name to describe their unique identity, and to help them talk to other children. For young children, the word *brown* works well; for older children, *biracial* or *multiracial* is helpful. Unfortunately, multiracial children often experience peers—and even adults—who express confusion about their identity.

- Provide books and other curricular materials that celebrate multiracial families. If the program or library does not have any, insist that they get some. With today's technology, it is also very easy to create books. Make sure that other displays in the program—pictures, doll sets, figurines, and so on—always include multiracial and multiethnic families, and intercede anytime someone questions the validity and naturalness of these families. When buying doll sets, family sets, and so on, mix some of them up; do not break all of them into racial and ethnic families and groups. Put pressure on manufacturers to develop books, dolls, and people with a large array of diverse physical characteristics that don't reinforce racial and ethnic stereotypes.

- Encourage parents in multiracial families to fill in "two or more races" on the federal forms

required by the program. Make sure the forms used provide this option (it is required by law).

- Provide activities, discussions, interactions, and exercises that focus on children's physical characteristics—skin color, hair color and texture, eye shape and color—but do not label or group children by race or ethnicity, and do not have them match their characteristics with parents and siblings, or with prototypes of various races.

- For older children (e.g., 6 to 8 years old) provide role models and historical characters who are multiracial: Frederick Douglass, the ballet dancers Marjorie and Maria Tallchief, John Audubon, Ralph Ellison, Bob Marley, and others.

- Provide parents with all sorts of resource materials to help them negotiate the challenges of raising mixed-race children in a race-fixated society.

- Be sensitive to unkind words, harassment, and bullying toward multiracial children by other children. This behavior can come from children of any race.

- Be sensitive to unkind words toward multiracial children from adults, including parents, teachers, and other staff. As has already been addressed, many people (including those from other countries) have negative views of parents who cross racial—and other—lines to marry, and they sometimes take this out on the children.

- Do not match classroom visitors or people you visit in the community with children in the program by race or ethnicity. This reinforces a single-race view of diversity.

- Respond to each parent and child as an individual. Don't make assumptions about their racial or ethnic identity. And be supportive. All families of young children struggle with a variety of conflicts and challenges. Multiracial families simply have one additional challenge—one that the program needs to address positively and supportively, and not make worse.

- Make sure that any diversity training, curricula, and programs that teachers and other staff

attend include multiracial children and families in their content, and affirm the right for these children to develop a full, multiracial identity. This applies to any multicultural college classes that teachers are required to take to improve their qualifications.

Music

In the 1990s, a survey of music teachers published in *The Psychologist* reported that over 75% believed that a special talent was needed in order to learn music. However, in contrast to this “folk psychology” view, the past two decades of neuroscientific research have generated findings that starkly contradict such a belief that musical ability is confined to a small section of the population. For example, when modern imaging technologies have been used to investigate how the brains of newborn infants respond to music, it is found that neonates have a sense of timing and beats (essential for the recognition of sound sequences in speech and music) and can respond to whether a melody is “in-tune” (consonant) or “out of tune” (dissonant). Newborns are also able to distinguish musical intervals (the differences between two pitches) and are sensitive to the kinds of harmonic structures (the combination of pitches) found in Western music.

This body of neuroscientific and related psychological evidence demonstrates that each human is born with the prerequisites needed to learn, make, and create music, and that musicality is an inherent component of human design in a way similar to, for example, the trait of bipedalism. Indeed, the fetus is capable of hearing throughout the final trimester inside the womb and so enters the world at birth with already significant experience of the maternal sound world.

This naturally raises questions as to why, in the light of the theory of evolution, humans have developed this general biological ability to make music, which, unlike bipedalism, does not seem to produce such an obvious benefit with regard to the

survival of the human species. The question of the relative usefulness or uselessness of music is pertinent in our determination of whether it has a core place in formal education, or whether it should be a largely extracurricular and perhaps solely pleasure-based activity.

In answering this question, the current evidence suggests that musical behaviors are widely represented in the brain, that learning musical skills physically restructures multiple areas of the brain by developing synaptic connections, and that engaging systematically in active music making over time appears to enable this more than any other human activity. Moreover, studies of other aspects of children's development suggest that there are potential increases in IQ measures, at least in the short term, with longer benefits evidenced in working memory, reading skills, spelling, foreign language learning, spatial skills, self-regulation, empathy, confidence, and sense of being socially included. This entry seeks to provide an overview of the nature and significance of children's early musical development and how this can be nurtured by appropriate educational strategies in order to provide benefits that are musical, cognitive, emotional, and social.

Benefits of Early Music Education

The most recent research on the benefits of learning music reveals that they can be lifelong and also places particular importance on the early years. During early childhood the brain undergoes enormous synaptic development that is unmatched in later life and the brain has a high degree of plasticity, that is, malleability to environmental influences. Many studies report that whether the child starts learning music before or after age 7 makes a difference with regard to several cognitive outcomes. For example, the corpus callosum, the nerve tract that connects the left and right hemispheres of the cerebral cortex, is found to be thicker in musicians who have started learning at age 7 or before; the ability to recognize melodic tones and produce accurate rhythm is stronger; and the ability to label heard pitches accurately on

a musical scale (termed *absolute pitch*) is more likely if you begin studying an instrument that needs tuning (such as a violin) before the age of 7. A recent overview of over 75 studies reported that sustained instrumental practice by children produces neurological changes associated with specific sound-related cognitive tasks.

What makes engaging in rich musical experiences a particularly fascinating opportunity in the field of early childhood education is that there appears to be no lower age limit at which to begin. For example, the Italian music educator Johannella Tafuri conducted a detailed longitudinal study of weekly music activities with mothers and their children that spanned 6 years and that began pre-birth when the mothers first attended the local conservatoire to begin a specially designed music program. She reported that participant children became much more advanced musically than expected.

In another early intervention study, 6-month-old babies were randomly assigned to groups that experienced music education inspired by Suzuki, had free play while listening to Mozart, or had no special music input. When all the babies' development was measured 5 months later, it was found those in the Suzuki-based group were significantly more advanced in their musical behaviors and also in their emotional, social, and communicational skills compared to the others, despite all babies initially being assessed at the same levels of development. It was significant that just hearing classical music did not produce any distinctive measurable benefits. The popular myth that listening to Mozart (or classical music in general) improves the intelligence of babies has been refuted in many studies, including by the researchers of the original, misinterpreted "Mozart effect" study.

However, although there is no general effect, music listening is reported to bring specific benefits, such as improving the resting condition of preterm infants, mitigating cognitive dissonance (discomfort caused by holding conflicting cognitions simultaneously), ameliorating pain in hospitalized children, and supporting visual acuity and cardiovascular function. Although listening to

music per se does not make children more intelligent, active and sustained participation in music making and in the learning of musical skills can produce numerous cognitive, emotional, and social benefits.

It is perhaps noteworthy that, before the invention of recording technology, the pleasure of listening to music—which is reported to stimulate the same evolutionarily critical brain regions as the cravings of sex and food—was inextricably tied to the act of performing, something that is still witnessed in tribal cultures around the world. Our Western culture is historically and prehistorically unusual in its conceptual separation of the act of performing from the act of listening.

Musical Interactions Between Parents and Young Children

Several ways in which active music participation can be experienced are already part of the "repertoire" of instinctual interaction between infants and their main caregivers, although parents rarely recognize these as a form of musical education. In diverse cultures around the world, parents have been found to speak to babies in particular ways that have distinctive musical features, such as exaggerated melodic contour, a prevalence of musical intervals that are common to the world's genres of music, and wide variations in vocal loudness. This "infant-directed speech" (also known as "motherese" and "parentese") accentuates the prosodic features of language (pitch and rhythm). Similarly, "infant-directed singing" tends to be higher in pitch, slower, and with exaggerated emotional features compared to normal singing. These features of parental voicing appear to be tuned to the ways that the brains of newborn infants are wired to comprehend.

Moreover, computer-based analyses on the vocalizations of babies with their mothers indicate that the mother and the baby engage in a form of musical conversation: taking turns with each other, and responding to the musical cues in each other's voices. In recognition of their powerful role in shaping such human–infant communication,

mothers have also been described as the first “mentors” of their children’s singing.

Furthermore, parents commonly play musical games with their infants, such as rocking or bouncing them rhythmically. Among the new findings on the effects of music on babies is the finding that bouncing babies to a regular beat (as opposed to doing random, irregular bounces) is likely to make the babies spontaneously more cooperative as a result and to an unprecedented degree. It has also been reported that 10-month-old babies spontaneously try to adjust their own movements (such as “jiggling along”) to match the beat of a rhythmic song that they are hearing. Indeed, in humans of all ages, it is found that simply hearing rhythmic music activates the motor regions of the brain; thus, instead of rhythmic engagement with music being thought of as something that humans need to “study,” it is perhaps better to consider this as a naturally developing response to sufficient and appropriate musical stimuli that can be nurtured.

Biological and Instinctual Bases of Music

Music is one of the earliest known forms of human cultural expression. According to evolutionary psychologist Robin Dunbar, from the University of Oxford, there is evidence that humans made music 500,000 years ago, presumably by means of vocal and percussive instrumentation. In contrast, speech is reported to have appeared only 200,000 years ago, and evidence is accumulating that instead of music being something on top of language (as suggested by one eminent psychologist), humans developed speech from their musical behaviors. In a similar way, a baby’s linguistic learning evolves from musical components of speech to verbal comprehension, and it is recognized that the neural networks for music overlap those of language. As mentioned earlier, musical activity in early childhood also supports parent–child interactions, as well as pro-social group relations in general.

Due to the biological and instinctual bases of music making, it is therefore important for any

form of early music education to build on these preexisting and naturally emerging abilities. Music education need not be thought of as simply musical instrument instruction, nor solely group singing, although both can be significant in the musical lives of children. Ideally, before children embark on formal music learning, such as in the sense of structured study, they should be encouraged to continue to be active music makers, building on their propensity to create and re-create musical artifacts.

Early Opportunities for Musical Activity

Children around the ages of 2 and 3 years are able to learn simple songs from their maternal culture, but they will also create their own versions, borrowing and adapting preexisting elements, improvising lyrics and musical features, and composing in real time as they explore, develop, repeat, and master elements of their experienced sound world. They are also programmed to “notate” such experiences if given the opportunity, such as by making marks that symbolize their sonic experiences. Musical notation is usually driven initially by young children’s sensorimotor experience, the physical “feelings” associated with making sound, such as banging a drum as an “action equivalent” of the motor behavior.

Invented notations typically will first indicate one perceived musical dimension (such as pitch or loudness) rather than several, which comes later. Such activities allow the young child to expand his or her musical understanding and build repertoire and musical vocabulary, which can form a positive foundation for subsequent musical learning that is more structured and shaped by systematic adult intervention.

As a baby turns into a toddler and a toddler into a preschooler, further opportunities arise for the development of musical skills. There are a variety of well-established examples of music education methods for children that are both structured and age appropriate, developed in various countries such as the Kodaly method in Hungary, the aforementioned Suzuki method in Japan, the Orff approach in Germany, and Musiikkileikkikoulu (“music playschool”) in Finland. Although these

methods are all different in their cultural origins, they share a child-centered approach where musical skills are built on aurally, experimentally, and playfully. Such music education is thus motivating and enjoyable for a wide range of children under school age.

Also, related to the earlier comments on invented notation, to focus music instruction on learning to play from standard notation is generally considered unsuitable for most young children, for the reason that it is teaching music “backward”; just like children first learn the language aurally and verbally before proceeding to read written text, musical development should follow a similar pathway of sound before symbol.

Overall, it seems clear that early years music educators should recognize the power of music, both as a central feature of a child’s basic human design, but also as a means of nurturing other aspects of the young child’s development. Music is important in its own right, but it will also contribute to physical, cognitive, social, and emotional development where children are provided with rich opportunities for sustained and active musical engagement.

MUTUAL REGULATION MODEL

Under the mutual regulation model, infant–caregiver meaning-making processes are a central mechanism governing both adaptive and maladaptive child outcomes. This view has two central tenets. First, infants, and adults as well, must make nonverbal biopsychological as well as nonverbal “meaning” about themselves with regard to the world of people and things. For infants these meanings coalesce in a rudimentary “biopsychosocial state of consciousness” that shapes their ongoing engagement with the world. To fail to make meaning is a psychic catastrophe. Second, infants and their engagement with the world are best understood from the perspective of open dynamic biological systems. As open systems, infants must constantly gain energy and meaningful information to maintain their organization and to increase its complexity and coherence—that is, to grow (Tronick, 2007).

The hypothesis behind the mutual regulation model is that these tenets are fulfilled by the operation of the infant–adult communication system, a dyadic mutually regulated system made up of two subsystems, infant and adult. In this dyadic system, emotional, behavioral, and biopsychological messages are exchanged between the partners about their intentions, expectations, and needs. This dyadic system for the infant scaffolds his or her engagement with the world of people, things, and themselves, and consequently their gaining of energy and meaning and continued existence and growth.

In the mutual regulation model (MRM), there is an exchange of intentions, meanings, and relational goals. It is a communicative system that is

mutually regulated. This is in contrast to early conceptions of the infant's mind: William James described the infant's world as "blooming, buzzing confusion," and John B. Watson said the infant's mind was a blank slate. During early work on the model, researchers surprised by the orderliness of infant-mother interactions used an analogy to the dancing of Fred Astaire and Ginger Rogers. The Fred-and-Ginger model also held that the exchange was made up of long periods of mutual gazing, positive vocalizing, and positive affect. Further research showed that a better analogy is to when Jennifer Grey and Patrick Swayze first begin to dance together in *Dirty Dancing*. Their dancing is made up of missteps, bumps against each other, tries, apologies, retries, brief match-ups, and missteps yet again. Thus the typical infant-mother "dance" is actually quite messy: It moves from coordinated, synchronous, matching meaning or intentional states to mismatched states and back to matching intentional states. The process, which can be called the process of reparation, is jointly carried out by the infant as well as the mother. The rhythm is match-mismatch-reparation, and when it goes well dyadic states of consciousness emerge, dyadic states of shared meaning (see Figure 1).

Interactive messiness emerges for many reasons, such as the partner's waning of attention or change of intentions, the tenths of a second speed of the interaction, and the infant's immaturity. Moreover, the infant at early stages of development makes meaning without language or symbols but with behavior and biopsychological processes, whereas the adult primarily uses language and symbols along with other processes. In some way the infant and adult can be thought of as two different species trying to communicate. To the extent that the communication works it is likely because adults still utilize infantile biopsychological processes to communicate and these are not completely overridden by language. Thus for whatever reasons the process of creating shared meanings is daunting; messiness is an inherent quality of infant-caregiver exchanges.

Research using micro-temporal analysis of videotaped interactions found that interactive mismatches were repaired the next interactive step 70% of the time at a reparation rate of every 3 to 5 seconds. Of course, the new matches were quickly followed by mismatches and those by the reemergence of new matches. The match-mismatch-reparation process was continuous but

Figure 1 The Process of Reparation/Creation of Meaning

led to the co-creation of new meanings. Further work indicated that mismatches are characterized by negative affect, stress, and dysregulation while matches are associated with infants' positive affect and engagement.

From the dyadic systems perspective of the MRM the reparation of interactive mismatches is essential for growth and is the key process for making new meanings. A paradigmatic example of creating new meanings is the infants' learning to play a game like peek-a-boo, which is analogous to, indeed no different than, the infant acquiring familial and culturally appropriate ways of being together with another person. The game and the being together reiterated time and time again and they are social and "arbitrary" or historical determined patterns. The infant learning peek-a-boo engages in bit-by-bit reparatory process of changing interactive errors (failing to respond, missing a cue, looking away too soon) into a coordinated dynamic game which, over months with repetition, comes to resemble what Jerome Bruner refers to as canonical form of the game, a form known to the adult. The same bootstrapping process underlies infants' demanding task of making sense of the unique cultural context into which they are born, a world that is historical, arbitrary, subtle, and contextualized.

In their world, infants must learn culturally specific ways of being with others, which likely demands the totality of infants' biopsychosocial capacity for meaning-making processes. Take one example of which there are many. Among the Gusii, a community of people in western Kenya, mothers look away when infants get too excited in face-to-face interaction. The looking away presages strict cultural rules about who can gaze at whom and with what emotion. The pattern is exactly the opposite of patterns in the United States where mothers increase the intensity of the interaction when mutual gaze is established. But think of both patterns as "games" that the infant eventually comes to know and make meaning out of via reiterated, messy interactive processes of reparation. Over time, with reparation the messiness is resolved, the games

are learned, and there is greater complexity and coherence in the interaction and the infant's state of consciousness.

Ed Tronick and Marjorie Beeghly have hypothesized that developing a successful reparatory history with a specific person via iterated interchanges such as those in peek-a-boo games or face-to-face play, whatever its cultural form, has positive developmental effects. It leads to an implicit knowing by infants that "*we* can repair mismatches" and to a sense of mutual trust. With the accumulation of successful reparations, infants come to know that their dysregulated emotional state and sense that "something is wrong" can be transformed into a positive state and concomitant feeling that "things are right," at least with this person. It generates attachment to other. Likely this process contributes to infants' emergent sense of agency and mastery (Beeghly & Tronick, 2011).

Moreover, the infant develops a positive mood, a positive affective core, and sense of well-being out of the iterated moment-by-moment experiences of positive affect. With this internalized positive affective core the infant, when engaging new people or situations, feels positive about a yet-to-be known engagement. Thus the moment-by-moment exchanges build up a kind of robustness or resilience. Infant moods in effect are Janus like; they, in an affective rather than cognitive way, bring the past into the present while they simultaneously bias expectations about the meaning of the about-to-be-experienced future.

When reparatory processes fail there are problematic outcomes. The face-to-face still-face (FFSF) paradigm illustrates the dramatic effects of reparatory failure. After a period of typical face-to-face play the adult takes on a neutral poker face and though looking at the infant refrains from touching or talking to the infant. The still-faced adult experimentally creates a prolonged dyadic mismatch. Following the SF in a reunion episode the caregiver resumes her normal interactive behavior, and reparation is again possible. The still-face with nonverbal infants generates infant solicitations, anger and distress, sadness and withdrawal. Older

verbal children may ask “what are you doing?” and demand that their mothers “talk to me.”

During the reunion episode there is a carry-over of negative affect and rebound of positive affect. The children display approach and avoidant behaviors, as the dyad attempts to repair the mismatch. In simulations of the still-face with adults there are similar reactions—anger, sadness, helplessness—even though there is no deception and the participants are fully aware of what is happening. In dyads with chronic reparatory problems we hypothesize they lead to an implicit knowing by infants that “we can’t repair mismatches,” “you cannot be trusted,” and “I am a failure.” Such reparatory failures can be seen in dyads with a depressed or traumatized parent or infants with medical problems such as prematurity. This sense of failure derails an infant’s sense of security and leads to an insecure attachment relationship.

Messiness in interactions and dyadic reparation are relevant and dynamic processes over the life span. John Gottman and Janice Driver (2005) argue that in adult couples, the experience of reparation (e.g., recovering from an argument) is fundamental to healthy robust relationships, in contrast to simply having smooth getting-along interactions per se. As argued by Tronick and Beeghly, in the clinician–patient relationship reparation of failure is foundational for building a strong therapeutic alliance. For young children who are continuously confronting new information and trying to make meaning of it, that is creating new and familial and culturally appropriate ways of being in the world, allowing for messiness and scaffolding its reparation is fundamental to their successful growth and development.

N

NATIONAL ASSOCIATION FOR THE EDUCATION OF YOUNG CHILDREN

The National Association for the Education of Young Children (NAEYC) works to ensure that all young children, birth through age 8, receive high-quality care and education. NAEYC members include child care professionals; infant, toddler, preschool, kindergarten, and primary teachers; center directors; primary school principals; college educators; trainers and mentors; policy makers; advocates; families; and others interested in the well-being of young children. NAEYC sets research-based standards to guide professional preparation and practice. The association provides numerous resources to help early childhood professionals and advocates for enhancing early childhood program quality; improving the professional development, practice, and working conditions of program staff; and helping families learn about and understand the need for high-quality early childhood education. Through position statements, work with other organizations, and its national voluntary accreditation systems, NAEYC promotes excellence in early childhood education for all young children from birth through age 8. This entry provides an overview of NAEYC's mission, programs, resources, and rich history, which is intertwined with the history of the early childhood field.

NAEYC's Guiding Statements

NAEYC's vision statement is that "all young children thrive and learn in a society dedicated to ensuring they reach their full potential" (NAEYC, n.d.). Its mission statement supports this vision:

NAEYC promotes high-quality early learning for all children, birth through age 8, by connecting practice, policy, and research. We advance a diverse, dynamic early childhood profession and support all who care for, educate, and work on behalf of young children. (NAEYC, n.d.)

The association has adopted a code of ethics for those working with young children based on these core values (NAEYC, n.d.):

- Appreciate childhood as a unique and valuable stage of the human life cycle.
- Base our work on knowledge of how children develop and learn.
- Appreciate and support the bond between the child and family.
- Recognize that children are best understood and supported in the context of family, culture, community, and society.
- Respect the dignity, worth, and uniqueness of each individual (child, family member, and colleague).
- Respect diversity in children, families, and colleagues.

- Recognize that children and adults achieve their full potential in the context of relationships that are based on trust and respect.

NAEYC's work is based on these core beliefs (NAEYC, n.d.):

- *Excellence and Innovation:* We are imaginative risk takers willing to challenge assumptions while being accountable to our mission and fiscally responsible.
- *Transparency:* We act with openness and clarity.
- *Reflection:* We consider multiple sources of evidence and diverse perspectives to review past performance, note progress and successes, and engage in continuous quality improvement.
- *Equity and Opportunity:* We advocate for policies, practices, and systems that promote full and inclusive participation. We confront biases that create barriers and limit the potential of children, families, and early childhood professionals;
- *Collaborative Relationships:* We share leadership and responsibility in our work with others. We commit time and effort to ensure diverse participation and more effective outcomes. We act with integrity, respect, and trust.

Based on this vision, mission, values, and beliefs, the organization adopted five priorities and goals in 2014 to guide the organization's efforts (NAEYC, 2014).

Strategic Priority 1: High-Quality Early Learning

Goal: Children birth through age 8 have equitable access to developmentally appropriate, high-quality early learning.

Strategic Priority 2: The Profession

Goal: The early childhood education profession exemplifies excellence and is recognized as vital and performing a critical role in society.

Strategic Priority 3: Organizational Advancement

Goal: NAEYC is a highly valued, credible, and visible organization.

Strategic Priority 4: Organizational Excellence

Goal: NAEYC reflects excellence in all aspects of organizational health and vitality.

Strategic Priority 5: Leadership and Innovation

Goal: NAEYC cultivates leadership and incubates innovative strategies that propel the field, profession, and systems of early learning.

Structure

NAEYC's governing board develops policies and procedures for the organization and is committed to helping the organization continually grow as a high-performing, inclusive organization that strives toward meeting its vision and mission. NAEYC employs a dedicated staff of professionals that carry out the work of the organization, led by an executive director and executive team.

NAEYC members are organized in networks of local and state affiliate groups, providing opportunities to collaborate with colleagues and work for the needs and rights of children in their communities, as well as at the national level. Affiliates are represented by an affiliate council, an advisory body that was formed in 2001 to provide a forum for networking and capacity-building among affiliates; provide recommendations for the organization, especially in regard to affiliate issues; and help develop a strong, inclusive leadership. NAEYC is committed to leadership development, providing resources, including conference scholarships and the NAEYC Legacy Leaders Fellows program. The association encourages participation from college students and early career professionals, as well as those at every other stage of involvement in the field.

NAEYC provides interest forums as a structure for members with similar interests and values to collaborate, network, and share ideas through online communities and meetings at conferences. The interest forums provide an avenue for discussion of diverse ideas and further the dialogue regarding topics relevant to the organization's mission. NAEYC interest forums include Asian; At-Risk and Special Needs; Black Caucus; CEASE/Violence in the Lives of Children; Children of Incarcerated Parents; Children's Global Issues; Early Childhood Science; Ethics; Faith Based; Family Child Care; Infant Toddler Professionals; Kindergarten; Latino Caucus; Lesbian, Gay, Bisexual, and Transgender; Men in Education Network; Nannies; Play, Policy, and Practice; Primary Grades; Student; Technology and Young Children; Tribal & Indigenous Early Childhood Network; Worthy Wage; and Young Children's Spirituality. NAEYC also has a number of panels and advisory groups that provide support to the organization and offer volunteer opportunities.

Publications and Resources

NAEYC has numerous publications and resources to enhance professional development and improve program quality. *Young Children* is its award-winning, peer-reviewed journal, published five times a year in both print and electronic versions with articles to meet the needs of early childhood professionals serving children from birth through age 8. *Teaching Young Children*, designed especially for preschool educators, has also won national awards and contains research-based, practical ideas preschool teachers can use in their programs. *NEXT for Young Children* and *NEXT for Teaching Young Children* are online resources that provide comprehensive training outlines that can be used with selected articles from each of the journals. *Early Childhood Research Quarterly (ECRQ)* is a scholarly journal with the latest research in the field, along with practical applications of the research. *Voices of Practitioners: Teacher Research in Early Childhood Education* is

a professional, online, peer-reviewed journal publishing the research of early childhood teachers.

NAEYC publishes books to support the professional needs of those working in the early childhood field. Topics include developmentally appropriate practices, child development, curriculum, leadership and management, anti-bias education, effective teaching, meeting standards, and other content relevant to the field.

NAEYC's website provides numerous resources for professionals, including position statements, selected journal articles, information about upcoming conferences and other professional development opportunities, public policy updates and resources, NAEYC accreditation information and support, and other initiatives of the organization. Its families website includes research-based information for parents on child development and learning, NAEYC standards and positions, and NAEYC accredited programs. The site also has materials that programs can share with families.

NAEYC's Center for Applied Research links research, policy, and practice. The center provides reports and research news posts on current issues, including play, assessment, and Common Core State Standards.

Conferences

NAEYC holds two national conferences each year where early childhood professionals can explore the latest in practice, policy, and research, as well as collaborate, network, and learn from one another. The NAEYC Annual Conference and Expo is the largest early childhood conference in the world. NAEYC also offers the National Institute for Early Childhood Professional Development each year for those who support the systems of early childhood program delivery and professional preparation and development.

Accreditation: To Improve the Quality of Early Childhood Programs

NAEYC sets standards of excellence for early childhood programs and professional practice.

NAEYC established a voluntary system of early childhood program accreditation, the National Academy of Early Childhood Programs, which was launched in 1985 after years of intensive study of the research, discussion, field testing, and feedback by thousands of members. In 2000 the Commission to Reinvent Accreditation was established and developed recommendations for the next era of NAEYC accreditation. NAEYC continues to review the accreditation criteria to ensure that they are important to quality, relevant, and based on current research. NAEYC provides resources and technical assistance to support programs interested in pursuing and renewing accreditation. NAEYC accreditation has been used by several states as the top rating of their quality rating and improvement systems (QRIS).

NAEYC is a constituent member of the Council for the Accreditation of Educator Preparation (CAEP), reviewing both initial and advanced early childhood professional programs in educator preparation programs seeking CAEP accreditation. NAEYC first developed early childhood teacher education guidelines for these programs in 1981, and has periodically revised and updated them to meet the current needs and challenges of the field.

NAEYC also has standards for early childhood professional preparation associate degree programs. With no formal body to ensure program quality, as there was for baccalaureate and graduate programs, NAEYC introduced a system to accredit these programs in 2003. The NAEYC Commission on Early Childhood Associate Degree Accreditation reviews applications and awards accreditation to associate degree programs that have demonstrated that they meet the NAEYC Professional Preparation Standards.

Public Policy

NAEYC is regarded as a leading voice in Congress and state legislatures. NAEYC's public policy goal is a well-financed, high-quality system of early childhood education for all children from birth to age 8. Its public policy work reflects NAEYC standards, position statements, and the research in the

field. In addition to its work at the national level, NAEYC provides support for members at the state and local levels. The NAEYC website provides information about current legislative issues and the legislative process. It provides tools to help members in their advocacy work, including contact information and links to members of Congress. Over the years NAEYC has built coalitions with other organizations to maximize impact, and has participated in a number of movements and alliances, including the White House Conference on Children in 1960 and 1970; the Alliance for Better ChildCare (ABC) in the late 1980s that led to the creation of the Child Care and Development Block Grant in 1990; the Stand for Children demonstration at the Lincoln Memorial in 1996, with over 300,000 individuals; and the Strong Start for Children—Building America's Future coalition, beginning in 2013.

Week of the Young Child

Every April since 1971, NAEYC has sponsored the Week of the Young Child to raise awareness of the importance of the early years of life. Local and state communities plan celebrations and events to educate the public about issues related to young children and their families and encourage them to take action to improve quality and access to high-quality programs for all young children. The week is also an opportunity to recognize programs and services that work to address critical issues for young children.

Developmentally Appropriate Practices and Other Position Statements

NAEYC develops position statements to outline the association's position on issues in early childhood practice, policy, and/or professional development for which there are controversial or critical opinions. They are developed through a consensus-building approach, bringing together diverse opinions and expertise, and seeking feedback from a wide audience. The aim of the position statements is to promote discussion on

important topics, establish shared language, promote investments, influence public policy, and build an evidence-based frame of reference and best practice.

With concern about the growing number of inappropriate practices and the push for more academic content to be taught in successively lower grades, NAEYC began work on defining appropriate practice and adopted a position statement on developmentally appropriate practice (DAP) in 1986. This was then extended and published as a book edited by Sue Bredekamp in 1987, with updated versions being released in 1997 and 2009. Developmentally appropriate practice is foundational to NAEYC's publications, training, accreditation, conferences, and other work, as well as for the field of early childhood. Developmentally appropriate practice involves meeting children where they are and helping them meet challenging but achievable goals. DAP is based on three core considerations, making use of what we know about: child development and learning; children's individual interests, abilities, and needs; and each child's social and cultural background.

Other NAEYC position statements include Quality, Compensation, and Affordability; Guiding Principles for the Development and Analysis of Public Policy; Media Violence in Children's Lives; School Readiness; Violence in the Lives of Children; Conceptual Framework for Professional Development; Responding to Linguistic and Cultural Diversity; Prevention of Child Abuse; Learning to Read and Write (developed with the International Reading Association); Developing and Implementing Policies to Promote Accreditation; Early Childhood Mathematics (developed with the National Council of Teachers of Mathematics); Early Learning Standards (developed with the National Association of Early Childhood Specialists in State Departments of Education [NAECS-SDE]); Early Childhood Curriculum, Assessment, and Program Evaluation (developed with NAECS-SDE); Standards for Professional Preparation Programs; and Technology and Interactive Media as Tools in Early Childhood

Programs (developed with the Fred Rogers Center for Early Learning and Children's Media).

History

NAEYC's rich tradition began in the 1920s when Patty Smith Hill began organizing professionals who were also concerned about the quality of the nursery school programs that were developing. Hill, along with Arnold Gesell, Abigail Adams, and 22 others, formed a National Committee on Nursery Schools to discuss the need for standards, innovative thinking, the qualifications of nursery school educators, and other issues of concern. The committee organized a national, public conference in 1926 in Washington, D.C., and officially organized in 1929 as the National Association for Nursery Education (NANE). Its first book was published that same year, *Minimum Essentials for Nursery Education*.

NANE was a member of the National Commission for Young Children, charged with being a clearinghouse on early childhood and child care information needed in the 1940s. It published a quarterly bulletin, issued legislative reports, and held biennial conferences. In the mid-1950s it invited other local, state, and regional organizations that were interested in nursery education to join it, with the stipulation that their members also be members of the national organization. By 1956 NANE had developed a structure with local, state, and regional affiliates.

In 1958, NANE formally incorporated as a not-for-profit corporation and established its headquarters office in Chicago with a half-time secretary. NANE reorganized to become the National Association for the Education of Young Children (NAEYC) in 1964, hired its first executive secretary, Cornelia Goldsmith, and changed the name of its journal to the current title of *Young Children*. In 1965 it had over 5,000 members and moved its headquarters to Washington, D.C. With the birth of the Head Start movement and the need for greater numbers of qualified staff, NAEYC became more active in providing leadership on professional preparation. Milton Akers helped in

these efforts, serving the organization as executive director from 1966 to 1972.

Marilyn Smith took over as executive director in 1973, working in a leadership team with J. D. Andrews, who served as chief operations officer. This team served NAEYC for the next 26 years. Concern for quality remained a leading issue for the organization, prompting it to plan a national accreditation system for early childhood programs, launching the system in 1985. That same year it organized the Council for Professional Recognition to administer the Child Development Associate (CDA) credential. This council became a separate organization in 1989.

Mark Ginsburg took on the role of executive director in 1999, and the organization purchased and moved to its current location at 1313 L Street in Washington, D.C. The organization celebrated its 75th anniversary in 2001. Jerlean Daniel served as executive director from 2010 to 2013. During this time, NAEYC initiated a multiyear national dialogue among the national, state, and local components of NAEYC to strengthen relationships and the capacity of the association at all levels. Barbara Willer, who served the organization in a number of guiding leadership roles for over 30 years, served briefly as interim director until Rhian Evans Alvin took on the role of executive director in August 2013. In recent years NAEYC has increased its electronic resources and has taken on innovative initiatives, promoting issues including professional development, strengthening families, and quality in-state systems. NAEYC's global presence has grown as countries around the world seek NAEYC's guidance. NAEYC has been responding with customized technical assistance and resources, as well as International Institutes and specialized conference offerings. Throughout its history, NAEYC has remained committed to working to improve the quality of care and education that all young children need and deserve, and providing the resources professionals need to achieve this vision.

NATIONAL ASSOCIATION OF EARLY CHILDHOOD SPECIALISTS IN STATE DEPARTMENTS OF EDUCATION

The National Association of Early Childhood Specialists in State Departments of Education (NAECS-SDE) is a membership association supporting the professionals leading a variety of federally funded and/or state-specific early childhood education and care programs. Over its 40 years of existence, the association has developed or codeveloped position papers that are intended to offer both guidance and support for maintaining an early childhood focus in state policy. All of the policy statements and position papers are posted on its website.

Members develop the NAECS-SDE positions, often in collaboration with other key national partners. Over the years, the association's positions, including positions on play, the Common Core State Standards for K–3, and attention to high-quality preschool for all, have guided members and others. A recent, comprehensive contribution of the association is the 2013 statement that attends to 10 powerful policies for the kindergarten year.

Early childhood, specifically birth through age 8, is a critical developmental period in which particular attention to the appropriateness of experiences matters. During this critical period it is important for the adults in children's lives to pay attention to maintaining a continuum of age and developmentally appropriate practices, especially when providing educational experiences. Education systems are generally bifurcated between the years prior to kindergarten and those after, with little regard for providing a continuum of development for the whole child utilizing standards of practice that promote the foundational dispositions necessary for future life and school success. In theory, a continuum of appropriate practices to support positive trajectories of growth for every child should be the norm. To foster appropriate practice

in the early grades, NAECS-SDE offers standards of practice beginning with the critical kindergarten year. The following highlight a few standards of practice, which are described further within the organization's policy statement on kindergarten:

- Kindergarten teachers with specialized training specific to early childhood are critical to implementing evidence-based instruction appropriate for kindergarteners.
- Deep connections with families are imperative.
- Selection of appropriate assessment tools and strategies is paramount to adequately capture the wide variation of development inherent in the early childhood years.

Kindergarten is the pivot point in linking the experiences that children have had in their homes, in their communities, and in any preschool experiences to the educational experiences of the K–12 world. Policies that guide the entrance into and programming for the kindergarten year all impact the effectiveness and power of the kindergarten year. In developing this policy statement, the specialists considered key elements, and rather than write extensively on each element, provided a statement that includes definitions, a synopsis of the current national landscape, an opinion of why the view matters for children, and links to research to support the viewpoint.

NATIONAL CENTER FOR CHILDREN IN POVERTY

The National Center for Children in Poverty (NCCP) is a nonpartisan public policy research center dedicated to promoting the economic security, healthy development, and well-being of low-income U.S. children and families. Established in 1989, the NCCP is part of Columbia University's Mailman School of Public Health, Department of Health Policy and Management. The center uses research to inform policy and practice, with the goal of ensuring positive outcomes for the next generation. Specifically, the NCCP focuses on the mutually reinforcing relationship between the economic security of low-income families and the healthy development of their children via its three focus areas:

1. *Family Economic Security*. Research has shown that low family income can impede children's

cognitive development and their ability to learn; contribute to behavioral, social, and emotional problems; and cause and exacerbate poor child health. The children at greatest risk are those who experience economic hardship when they are young, with poor outcomes being most severe among those who suffer through harsh and chronic hardship. This unit identifies and promotes what is needed to help families succeed and support their children, including employment, wage, and job training policies; work supports such as the Supplemental Nutrition Assistance Program (food stamps), Temporary Assistance for Needy Families (welfare), the Earned Income Tax Credit, child-care subsidies, and family leave insurance.

2. *Early Childhood*. As early as 18 months, children in poverty show significant lags in their development. NCCP promotes the most effective supports for poor children's healthy development in the critical years from birth to the early grades, a time when experiences in the home, community, and school shape a child's chances of success and well-being throughout the life course. These include access to home visiting, quality child care, and early intervention.

3. *Health and Mental Health*. Access to health and mental health care as well as the quality of the care provided play a major role in children's chances for success in school and in life. NCCP evaluates and identifies effective health and mental health policies and programs that support poor children's positive development.

Making Research Accessible

With staff representing a wide range of disciplines, the NCCP conducts original research but also monitors a vast body of national and state-level demographic and policy research. It gathers, evaluates, and synthesizes the most timely and significant findings, using the information to develop fact sheets, policy briefs, and web-based tools, and making it available via its website. An average of 60,000 users visit the website each month, accessing its

publications and user-friendly web-based tools to retrieve, analyze, and compare data.

Child Care & Early Education Research Connections

NCCP also operates Child Care & Early Education Research Connections, a web-based, interactive database of research documents and public use datasets from major child care, Head Start, and early education research and evaluation studies that can be used to conduct secondary analyses on topics related to early care and education. Among other things, Research Connections does the following:

- Houses and topically classifies an expansive, multidisciplinary collection of research reports, syntheses, and other critical information related to child care and early education, and in particular, children in low-income families

- Provides technical assistance and training to researchers and policy makers

- Commissions and develops reviews of research, research-to-policy briefs, and key topic resource lists, and provides bibliographies on policy-relevant topics

NCCP launched Research Connections over a decade ago with funding from the Office of Planning, Research and Evaluation, Administration for Children and Families, and in partnership with the University of Michigan's Inter-University Consortium for Political and Social Research.

NATIONAL EARLY LITERACY PANEL

The National Early Literacy Panel (NELP) was appointed in 2002 to review the scientific research literature on the teaching of literacy to preschool and kindergarten children. The panel worked under the auspices of the National Center for Family Literacy, and was funded by the National Institute for Literacy in consultation with the National Institute of Child Health and Human Development, the U.S. Department of Education, and the Head Start Bureau of the Department of Health and Human Services. NELP issued its report, *Developing Early Literacy: Report of the National Early Literacy Panel*, in 2008. This study reported the results of a series of meta-analyses of approximately 500 studies on early literacy development and instruction, and it remains the most ambitious review of preschool literacy research yet conducted.

Purpose of the Panel

In 2000, the National Reading Panel (NRP) issued an analysis of research on reading instruction that focused on grades K–12. NELP was appointed to conduct research reviews that would extend the NRP findings to the preschool years, to ensure that programs like Head Start would have the same access to research on instructional effectiveness available to elementary and secondary schools.

Specifically, NELP set out to determine, on the basis of empirical research, (1) the skills and abilities of young children that predict later reading and writing outcomes, (2) the instructional approaches that lead to gains in those skills and abilities, and (3) the child characteristics or instructional conditions that mediate or moderate the effects of instruction on young children's literacy development.

Panel Members

Members of the panel included Timothy Shanahan (panel chair), University of Illinois at Chicago; Anne Cunningham, University of California,

Berkeley; Kathy C. Escamilla, University of Colorado; Janet Fischel, State University of New York at Stony Brook; Susan Landry, University of Texas Health Science Center at Houston; Christopher J. Lonigan, Florida State University; Victoria J. Molfese, University of Louisville; Chris Schatschneider, Florida State University; and Dorothy Strickland, Rutgers University. Laura Westberg of the Center for Family Literacy played a significant role in the work.

Methodology

NELP conducted extensive electronic searches that identified 8,000 potential articles; panel members then screened these articles to determine their relevance to the research questions and their consistency with selection criteria established by the panel. Ultimately, approximately 500 articles were used in the various meta-analyses that were conducted. These analyses summarized correlational data exploring the relationships among children's early abilities and skills and their later literacy development, and experimental results that revealed the impact of instructional interventions on children's learning during the preschool years.

The panel first identified early skills that were precursors of later literacy achievement. This was important since few preschoolers are able to read in any conventional sense so effective preschool literacy programs have to be evaluated in terms of their ability to teach successfully skills that lead to higher literacy achievement. To identify precursors the panel analyzed studies that reported correlations between early skill attainment and later achievement in decoding, reading comprehension, or spelling.

Unlike the NRP that asked questions about the effectiveness of specific instructional approaches and then sought evidence on these approaches, NELP considered the results of all published experimental studies that examined literacy instruction with preschool and kindergarten children. This meant that the panelists, once they had identified the universe of studies,

had to organize them into related sets. Consequently, the studies provided information about five instructional approaches: instruction that taught children to crack the alphabetic code, shared reading interventions, parent programs, preschool/kindergarten programs, and language enhancement interventions.

Research Findings

NELP identified six early skills that had high correlations with later literacy as shown by data drawn from multiple studies with large numbers of children. These variables maintained predictive power even when other potential influences were accounted for. They included alphabet knowledge, phonological awareness, rapid automatized naming of letters/digits and objects/colors, phonological memory, and name writing. Additional precursor skills that were moderately correlated with later literacy achievement included oral language, concepts about print, print knowledge, reading readiness, and visual processing. NELP used these predictors, along with measures of conventional reading and spelling (e.g., decoding, fluency, comprehension), as outcomes in the evaluation of preschool and kindergarten teaching approaches.

NELP found that teaching phonological awareness, letter sounds, and decoding led to marked improvements in early literacy outcomes and conventional literacy skills. Book sharing interventions improved children's print knowledge and oral language skills, and parent programs improved oral language skills and general cognitive abilities. Studies of preschool and kindergarten programs found significant impacts on spelling and reading readiness, while language interventions had large impacts on children's language skills.

NELP, for the most part, was unable to determine whether child characteristics influenced the effectiveness of the instructional interventions. In general, age, socioeconomic status, and race did not alter the effectiveness of the interventions. One exception is that the language interventions showed greater effectiveness in preschool than kindergarten.

Few interventions improved conventional literacy skills or the precursor skills most related to later literacy growth; the exception being code-emphasis interventions. Code-emphasis interventions that produced large and positive effects on conventional literacy were usually teacher-directed lessons delivered one-on-one or through small-group instruction. Almost all of these efforts focused on phonological awareness (e.g., having students detect or manipulate small sound units of words). Teaching children about the alphabet (e.g., letter names or letter sounds) or simple phonics tasks (e.g., blending letter sounds to make words) enhanced the effects of phonological awareness training during these years.

NATIONAL HEAD START ASSOCIATION

The National Head Start Association (NHSA) is a not-for-profit organization that works in support of the 1,600 Head Start grantees in the United States and the 1 million children and 200,000 staff members involved in Head Start programs.

NHSA advocates for changes in policy so that all eligible children can benefit from the Head Start model of support for the whole child, the family, and the community.

Mission and Vision

As noted on its website, NHSA's vision is

to lead—to be the untiring voice that will not be quiet until every vulnerable child is served with the Head Start model of support for the whole child, the family and the community—and to advocate—to work diligently for policy and institutional changes that ensure all vulnerable children and families have what they need to succeed. NHSA's mission is to coalesce, inspire, and support the Head Start field as a leader in early childhood development and education. (NHSA, n.d.)

History

Head Start began in the summer of 1965, serving more than 500,000 children in a national commitment to children in poverty by providing comprehensive services to help prepare them and their families to begin school. Over the next 50 years, more than 31 million children have attended Head Start, and extensive research documents how the program has enabled them to succeed in school and in life.

Mirroring the history of the Head Start program, NHSA was formed and grew to scale quickly. The idea for a Head Start Association came out of a national conference for directors of community action agencies in 1973 in Kansas City, Missouri. Some of the Head Start program directors attending the conference discussed the need for a national association that could advocate for the Head Start community in Congress. They were concerned by the Nixon administration's threat to eliminate community action agencies that at that time sponsored the majority of Head Start programs.

This core group of directors met with other Head Start directors from across the country, pooled their resources, and formed the National

Directors Association. The directors passed a resolution to invite Head Start parents to form an affiliate association. At this request Head Start parent delegates from each state met in September 1974 to form the Head Start Parents Association. At a January 1975 meeting, non-director staff members formed the third affiliate association, the Head Start Staff Association. Later, a fourth association, Friends of Head Start, was formed, involving supporters of Head Start who did not fit into any of the other categories.

The Third Annual Head Start Conference was held in May 1976, in New Orleans, Louisiana. This meeting represented the combined efforts of the four associations and participation was overwhelming. The National Head Start Association was catapulted into a new level of mass conference planning. At the Fourth Annual Meeting held May 19–22, 1977, in El Paso, Texas, the first official officers of NHSA were elected. Rosalie Carter-Dixon of Newton, Massachusetts, was the first president.

The members of NHSA's four affiliate associations voted to merge into one association on June 7, 1990. In the new structure, Head Start directors, parents, staff members, and friends became members of one association, distinguished by a different membership class designation. This simplified the association's structure, unified its members, and helped clarify its mission of bringing together all members of the Head Start community. Now, the geographic Head Start regions, the community involved in American Indian/Alaska Native Head Start programs, and the community involved in Head Start programs for migrant and seasonal farmworker families each sent four members to the NHSA Board: one parent, one staff member, one director, and one friend.

Advocacy Impact

Throughout NHSA's history, it has had good working relationships with the federal Office of Head Start and successfully worked to maintain bipartisan support from Congress and the White House.

The Carter Administration

During the Carter administration, NHSA mobilized thousands of letters from every state in an effort that contributed to an increase of \$190 million in final budget allocations to Head Start.

In 1979, President Carter tried to include the program under the newly established Department of Education. Head Start leaders met with key congressional and administration officials to block the move, and Head Start parents joined the effort—a group from Connecticut traveled by bus all night to Washington, D.C., to talk to their senator. The congressional committee reviewing the proposal recommended that Head Start remain in the Administration for Children, Youth and Families (ACYF). In 1979 the Head Start program was reauthorized for 5 years, with funding authorized for a 20% increase each year in the number of children and families served.

The Reagan Administration

In 1981, a block grant proposal aimed to cut the program's budget by \$130 million. The proposal was thwarted by an outcry from NHSA parents, staff, and friends. A federal Head Start strategy paper proposed giving states more responsibility for administering programs but cutting costs across the program's services, monitoring, and evaluation. NHSA launched a massive campaign in protest to these recommendations. As a result of these efforts, established services were maintained. In fact, an increase of \$125 million was allocated for the 1982 fiscal year.

The 1984 reauthorization of Head Start was carefully drafted to ensure that (1) funds would be available for training on an ongoing basis, (2) the National Child Development Associate (CDA) program would continue, (3) Head Start's Performance Standards would be strong, and (4) Head Start services could be provided to each child for 2 years. NHSA and advocacy partners were successful in pushing Congress to complete the reauthorization before adjourning.

In 1987–1988, Head Start was reauthorized again, for 4 years. In 1988, Congress appropriated more than \$50 million for Head Start salary improvements, a long-sought NHSA goal. Thousands of thank-you letters were sent.

The George H. W. Bush Administration

Head Start's 1990 reauthorization included set-aside funds for quality improvement; a 2% reserve for training; expansion of Parent–Child Centers; minimum teacher qualifications, where every classroom must have at least one teacher with a Child Development Associate (CDA) degree or appropriate early childhood degree or credential; comprehensive reports to Congress on Head Start biannually; a longitudinal study of Head Start; and additional clarifications to the law.

The Head Start Improvement Act in 1992 made possible the purchase of facilities, extended waivers for nonfederal regulations, established transportation regulations, provided for health services to younger siblings, protected the quality set-aside, called for the review of new grantees after 1 year, provided literacy and child development training to parents, and eliminated priority status to a grantee once funded.

The Clinton Administration

The Head Start Reauthorization Act of 1994, enacted with bipartisan sponsorship and support, made a number of changes to ensure that all Head Start children and families were offered high-quality services, and played an important role in expanding Head Start through the creation of Early Head Start for pregnant women, infants, and toddlers, and overall improvement in the quality of the programs.

A new Congress determined to slash the federal deficit. In fiscal year 1996, the Head Start community raised its voice and gained a small increase of \$36 million for Head Start. With the Head Start family once again playing a strong role in appropriation debates, Head Start secured \$411 million and \$374 million increases for fiscal years 1997 and 1998, respectively.

The George W. Bush Administration

George W. Bush, elected president in 2000, advocated moving Head Start to the Department of Education and funding it through a block grant to individual states. NHSA and the Head Start community, citing the importance of the federal-to-local funding structure of Head Start and the value of having a program focused on comprehensive services to children and their families, succeeded in keeping the program under the auspices of the Administration for Children and Families in the Department of Health and Human Services.

Head Start was reauthorized again in 2007 in the Head Start for School Readiness Act, which included numerous provisions intended to enhance the program's focus on school readiness. These included increased degree requirements for teachers, memoranda of understanding with local school districts to improve transition, a call for required use of scientifically valid curricula, and the creation of Centers of Excellence so exemplary programs could share their expertise. In addition, the 2007 act made homeless children categorically eligible. Finally, the act called for a system to identify low-functioning programs and require them to compete for funding with other potential providers.

The Obama Administration

During the Obama administration, the program enjoyed the support of the White House. Yet the 2011 Budget Control Act and the resulting sequester led to a 5.3% cut to Head Start and Early Head Start programs across the country. In 2012–2013, programs served 57,000 fewer children as a result of cuts. In addition, the government shutdown in October 2013 would have forced numerous programs to close had it not been for NHSA's quick work to secure philanthropic support to keep them open.

In 2014, following a year of relentless advocacy, funding that was cut in the sequester was restored to Head Start, and Congress allocated an additional \$500 million for new investments in

Early Head Start Expansion and Early Head Start–Child Care Partnerships. NHSA strongly advocated for the expansion option for rural communities and for time to establish successful partnerships. Grant awards were announced in December 2014.

Leadership

In 2009, Yasmina Vinci became NHSA's executive director. Vinci was principal and founder of EDGE Consulting Partners and the founding executive director of the National Association of Child Care Resource and Referral Agencies (NACCRRA). At NACCRRA, she led the transition from an all-volunteer association of 200 child care resource and referral agencies to a powerful national network of more than 860 community-based organizations, now Child Care Aware of America.

NHSA Organization

Beginning in 2014, NHSA reorganized its programs under a central Knowledge Center, designed to be an infrastructure that generates, curates, communicates, and connects knowledge across different topic areas related to families, programs, researchers, and policy makers. Within the Knowledge Center are four centers that organize NHSA's efforts to support practitioners and advance the future of the Head Start program. Wrapped around this work are partnerships with advocacy organizations and resource organizations that support Head Start programs and NHSA in meeting the needs of the most vulnerable children and families in the United States. In parallel to decades of advocacy efforts, NHSA has worked to create tools ranging from early literacy materials to the *NHSA Dialog* journal to connect researchers and practitioners to the newly launched *Go Smart!* app to help parents and teachers fight childhood obesity.

The Center on Advocacy

The NHSA Center on Advocacy will use grassroots action, parent-driven support, and a

nonpartisan strategy to organize national, state, and local activities to ensure a sustainable future for Head Start. The center hosts Leadership Institutes to educate Head Start leaders as advocates and help them build relationships with their representatives.

The Center for Effective Practice

The Center for Effective Practice engages organizations committed to Head Start children and families to identify, create, and share knowledge, resources, and communities of learners to deepen understanding of best practices in early education. Information provided by the Center for Effective Practice is evidence based and meant to help organizations maximize resources and produce optimum outcomes. Each year, conferences for Head Start parents and staff share best practices, innovations, and new ideas.

The Center for Policy, Data, and Research

The NHSA Center for Policy, Data, and Research generates new knowledge to lead reform for stronger child and family outcomes, informed by outstanding practices from the Head Start community.

The Center on the States

The Center on the States cultivates, supports, and positions innovation and best practices in state-based early learning systems. The center supports the work of state Head Start communities through a network of affiliates to build visionary leaders, trusted partners, and tireless voices for vulnerable children and families in their states.

Fifty years after the creation of Head Start, the need for advocacy continues, and the National Head Start Association is leading the field in innovating for the future.

NATIONAL INSTITUTE FOR EARLY EDUCATION RESEARCH

Founded in 2002, the National Institute for Early Education Research (NIEER) supports excellence and equity in early childhood education by conducting and disseminating nonpartisan research and policy analysis. The institute's signature product is an annual report, now in its 11th year of publication, on the state of preschool in the United States. The *State of Preschool Yearbook* is based on a survey of all state-funded pre-K programs (currently operated by 41 states and the District of Columbia) that tracks state policies including eligibility and enrollment, operating schedules, program standards, personnel, monitoring and evaluation, and funding. In addition, the institute seeks to conduct field studies that use the most rigorous possible methods in order to produce research that can yield clearly interpretable findings. NIEER conducts evaluations of program effectiveness, research and development regarding curriculum and professional development, research and development of assessments of teacher practice, research and development on the Early Learning Scale for children, and a wide range of policy analyses. The institute conducts

research internationally as well as within the United States. Dissemination efforts of the institute include a website with an extensive collection of policy briefs, research reports, links to journal articles, videos, and a news archive. The website receives millions of hits each year. In addition, NIEER publishes a biweekly electronic newsletter and a blog reaching more than 6,000 readers. NIEER also maintains a Facebook page and a Twitter account with more than 11,300 followers. The institute leads the Center for Enhancing Early Learning Outcomes and with its partners in this enterprise (i.e., Educational Development Corporation and Council of Chief State School Officers) provides extensive technical assistance to state education agencies. Together with the Korea Institute for Child Care and Education, the institute publishes an open-access peer-reviewed journal through Springer, the *International Journal of Child Care and Education Policy*.

NIEER is directed by W. Steven Barnett, an economist and Board of Governors Professor at Rutgers University. He leads a diverse team that carries out the institute's research using their combined backgrounds in education, human development, developmental psychology, public policy, economics, sociology, and statistics. This team has been a leading advocate of the view that public and private spending on young children has an important investment component and that research ought to inform policy makers and the public about the costs and benefits of early care and education policies, programs, and practices from that perspective. In addition, NIEER has advanced the view that policy recommendations should not be made based on individual studies, but taking into account all of the relevant science. For this reason, NIEER produces a series of policy briefs (*Preschool Matters*) that summarize the evidence across disciplines on specific topics relevant to early childhood policy. In addition, NIEER has conducted major meta-analyses and other reviews of research on the long-term impacts of early childhood programs (broadly defined) on children's learning and development. Among the most notable are a meta-analysis of research in the

United States on early care and education program impacts led by Dr. Greg Camilli; a meta-analysis of the international research on early intervention impacts on cognition, social-emotional development, nutrition, and health led by Dr. Milagros Nores; and an essay review on the sources and nature of variations in impacts on learning and development in the years after children leave early childhood programs and enter public schools by Dr. Barnett that was published in *Science*.

NIEER partners with the Educational Development Corporation headquartered in Boston and the Council of Chief State School Officers to operate the Center on Enhancing Early Learning Outcomes (CEELO). CEELO is charged with strengthening the capacity of state education agencies (SEAs) to lead sustained improvements in early learning opportunities and outcomes for children from birth through age 8. CEELO convenes workgroups to respond to SEAs' identified and emerging needs, as well as participant-led affinity groups to support peer-to-peer learning, and collective efforts to address CEELO's five priority goals; produces research-based materials disseminated through the web (ceelo.org) to guide SEAs decisions regarding policy and practice; provides a 50-state database with key benchmarks on SEAs policies and initiatives; conducts topical webinars and an annual national "RoundTable" to engage all 50 states in sustained examination of key policy issues and promote SEAs leadership development; and delivers targeted support and consultation to states to meet their individual needs.

The *State of Preschool Yearbook* is based on an annual survey that has traced funding, access, and policies of state preschool programs since 2002. The yearbook survey was initially developed and supported with funding from the Pew Charitable Trusts. In recent years the survey has been funded by the U.S. Department of Education's National Center for Education Statistics. The survey is a critical resource for policy makers, academics, the media, and others seeking to understand state policy and its consequences. The survey also brings greater transparency to state preschool education

policy. The survey collects responses to more than 100 survey questions that have been administered consistently for more than a decade. All of the historical data are archived and available for general use by the public.

In collaboration with state agencies and other research organizations, NIEER conducts evaluations of the effectiveness of preschool programs throughout the United States, primarily at the request of state and local governments. In addition to publishing studies in academic journals, NIEER archives its evaluation reports at nieer.org. NIEER employs a wide range of research designs, quantitative and qualitative, as appropriate to address policy makers' questions. Examples of this evaluation research include the following impact studies: an evaluation of the Arkansas Better Chance preschool program; an evaluation of New Mexico's state-funded preschool program; and a series of evaluations of New Jersey's Abbott program, which provides full-day, high-quality preschool education beginning at age 3 to all children in 31 districts that now extends through Grade 5 and finds substantial and sustained gains in educational achievement as well as reductions in grade repetition and special education placements. NIEER currently is conducting an evaluation of the AVANCE parent-child program, an intervention that begins with families in the first 3 years of a child's life.

NIEER has conducted extensive research on who participates (and does not participate) in early care and education programs, investigating participation patterns nationally and in states to assess the extent and sources of disparities in participation rates. An early example of this research is "Who Goes to Preschool and Why Does It Matter?" (2004; by W. Steven Barnett and Donald J. Yarosz), Number 7 in NIEER's *Preschool Policy Matters* series. This study found that pre-K attendance rates remained highly unequal and that many of those who might benefit most from pre-K participation did not attend. A key contribution of NIEER's work has been to point out that differences in participation rates—lower rates of participation by Hispanics, for example—cannot simply be attributed to differences in demand as they also

reflect geographic differences supply created by federal and state policy. NIEER also has examined variations in participation rates within states.

Another key area for research by NIEER is to evaluate the costs and benefits of alternative program design features. For example, NIEER conducted a randomized trial of the *Tools of the Mind* curriculum. This curriculum explicitly seeks to enhance executive functions as a means to improve child development holistically. In comparison with a more conventional preschool program, *Tools* was found to produce academic gains that were at least as large while producing much greater improvements in classroom behavior. An in-depth investigation conducted with Adele Diamond (published in *Science*) found significant improvements on well-designed, highly specific measures of executive function. The *Tools* curriculum is not significantly different in cost, but it does require an investment in training and time to develop to mature implementation as it differs considerably from typical practice in American preschools. Another influential example of this research is NIEER's randomized trial comparing English immersion to dual language (Spanish–English) immersion preschool education. The dual language immersion model had no additional costs and produced equal gains in English language development and mathematics while advancing Spanish language proficiency. Finally, NIEER conducted a set of randomized trials with the Chicago Public Schools to compare alternative approaches that might enhance children's learning and development including a longer day, class size reduction, parent engagement, and increased coordination from preschool through the early grades. Costs of the enhancements, as well as their impacts on language, literacy, and mathematics, were measured. Results were expected in 2015.

The institute has a strong interest in early care and education outside the United States, including in developing countries where some 200 million children have compromised development due to underinvestment. With public and private sector partners, NIEER has been conducting a randomized trial of an intervention through full-day child

care from birth to age 5 in two disadvantaged communities in Colombia. This study can be considered a rough replication of the landmark Abecedarian study in a new context with a sample that is an order of magnitude larger than those in the Abecedarian study and other landmark randomized trials. The intervention is a comprehensive nutritional and educational program and the study examines cognitive, linguistic, nutritional, and social impacts over the long term. Initial findings will be published in 2015.

NIEER has developed, implemented, and evaluated multiple initiatives that foster high-quality early science, technology, engineering, and mathematics (STEM) teaching and learning for all young children. Efforts, led by Drs. Alissa Lange and Kimberly Brenneman, have focused on professional development, curricula, family engagement, dual language learners, and home–school–community connections. Funding from public and private sources has supported a range of studies. For example, NIEER is engaged in two multiyear projects funded by the National Science Foundation to create and evaluate an innovative preschool professional development model around STEM, with supports for dual language learners. Results of this work have been disseminated at national conferences, and findings will be published in 2015–2016.

NIEER also conducts assessment development. Through extensive field research, NIEER identified needs not met by existing assessments of both classroom practice and children's learning and development. Researchers at NIEER have collaborated with other experts to respond to these needs to measure development. First, the *Preschool Rating Instrument for Science and Mathematics* (PRISM) is a classroom observation tool that measures the presence of classroom materials and teaching interactions to support mathematics and science learning. PRISM places a lens on math and science content-specific quality in early childhood classrooms that had previously been absent from the field. Second, the *Classroom Assessment of Supports for Emergent Bilingual Acquisition* (CASEBA) measures, through observation, the quality of language and literacy supports teachers

offer children with a focus on dual language learners (DLLs). CASEBA has a partner instrument for professional development, *Self-Evaluation of Supports for Emergent Bilingual Acquisition*. Third, the *Teacher Survey of Early Education Quality* (TSEEQ) is a self-report survey completed by early childhood teachers regarding their classroom practices and quality. This instrument is a potential proxy for expensive and time-consuming classroom observation. Lastly, NIEER research staff recognized that early childhood teachers were becoming overwhelmed by child assessment and were not using the data collected to inform instruction. The *Early Learning Scale* (ELS) is a streamlined systematic observation-based assessment of preschool and kindergarten children to allow teachers to assess children's progress toward learning standards in a manageable and useful way.

Finally, as a unit of Rutgers University, NIEER is highly engaged in supporting New Jersey's state and local education agencies in their efforts to continuously improve early care and education. In addition to studies previously mentioned, these efforts include a statewide study of the quality of infant-toddler programs, validation of the state's quality rating and improvement system, an evaluation of the quality of preschool and kindergarten programs serving children with disabilities, training and technical assistance in self-evaluation and continuous improvement in kindergarten, and development and provision of professional development for guidelines for effective practice in first through third grades.

NATURE AND YOUNG CHILDREN

The ways young children experience nature have changed in recent decades. Today children are more likely than ever before to be disconnected from the natural world. This limited contact with nature negatively affects the growth and development of the whole child. In addition, young learners are losing the opportunity to connect with nature and develop an understanding of their place in the natural world. This entry will focus on reasons why children's experiences in nature have changed, the benefits of spending time in natural playscapes, and developmentally appropriate ways to incorporate nature into children's daily experiences.

Reasons for Change in Children's Nature Experiences

Today's children spend an average of only 4 to 7 minutes a day outside. This limited outdoor time can be attributed to several cultural changes and developments. First, children are exposed to many different technological devices at a young age. These devices have become a part of many family routines. As a result, young children often experience virtual nature rather than getting outside and exploring, either on their own or with a caring adult. Instead of spending time in nature they watch it on a screen. On average, children spend more hours participating in screen activities than they do in school each year.

Parents are often afraid to take their children outside or allow them to explore on their own. They are conditioned by the media coverage of neighborhood crime, child abductions, insect-borne diseases, and various forms of pollution. Walking or riding a bicycle to school was once considered a routine part of childhood. Today young children may spend as much as 2 hours a

day on the school bus. Those who live close to the school are not encouraged to walk to or from school due to parental worry, time constraints, or extracurricular commitments.

Another cultural change occurring in recent decades is the overscheduling of young children's lives. Parents are pressured to enroll their children in sports and other extracurricular activities before even starting kindergarten to give them an advantage later in life. Schools are limiting and sometimes even omitting recess to provide teachers with more instructional time to better prepare young learners for standardized tests and meeting state and national learning standards. Self-directed exploration and play in the out of doors is no longer valued as a necessary part of childhood.

The essence of play itself and natural play environments have dramatically changed in recent decades. Children are so programmed, tested, and pressured to get ready for the next level of school that they have little or no experience with fantasizing, wondering, wandering, or experiencing the pleasures of carefree, idle days. In addition, they have access to fewer wild places. Many children's play areas and school yards have become urbanized with manicured fields, artificial surfaces, and manufactured climbing equipment.

Teachers, caregivers, and parents do not value time spent outside and often fear children asking questions to which they don't know the answers. Adults may feel uncomfortable in the outdoors due to their own limited experiences and concern over weather conditions. Many feel nature can only be experienced when the weather is perfectly suited for both adult and child.

Benefits of Spending Time With Nature

Self-directed, exploratory play in a natural environment influences children's growth, development, and attitudes about the environment in a variety of ways. The well-being of young children, both physically and mentally, is influenced by their interactions with the natural world. Research indicates that children who spend time outside in natural playscapes (a) are less likely to be obese;

(b) have more developed motor skills; (c) experience more focused attention and less stress (especially for children diagnosed with attention-deficit/hyperactivity disorder); (d) develop critical thinking and problem-solving skills; (e) gain a deeper understanding of life cycles and seasons; (f) display more diverse imaginative and creative play behaviors; (g) are more aware of the interdependence among plants, animals, people, and environmental elements; and (h) acquire a personal connection and stewardship for nature that extends throughout their lives. Studies have shown that children who spend time with nature show increases in their motivation to learn, self-esteem, creative play, and cooperation. Spending time in nature allows children the opportunity not only to discover information about the environment but also to enter into a rich and complex relationship with nature.

Developmentally Appropriate Ways to Share Nature With Young Children

Connecting children with nature is essential for optimal growth and development in all developmental domains, vital for fostering attitudes about and understanding of the environment, and necessary for providing individuals with inner sources of strength and healing during stressful times. There are numerous ways that caring adults can foster children's and their own relationship with the natural world.

Nature is best learned about in nature—exploring, discovering, investigating, adventuring, and experimenting. Nature explorations, activities, and experiences should begin simply and focus locally. Children need time to investigate at their own pace in local, natural playscapes. This might include backyards, school playgrounds, or natural areas in the community. In addition, children need these outdoor experiences on a routine basis in all kinds of weather. Emphasis on discovery and relationships in a warm, nurturing atmosphere help children feel secure in their exploration and build skills. Adults who model interest and wonder, sharing their own observations as they marvel at

those made by the children, assist children in building relationships and making connections with the natural world.

Whenever possible, children's natural curiosities should be honored and explored. Developmental levels must be considered when planning experiences for young children. They are not yet intellectually, socially, or emotionally prepared to learn about or take on the environmental problems of the world but rather need time to explore, understand, and love their local environment. Following the child's lead promotes learning experiences where everyone is actively involved. Capitalizing on children's natural inclinations toward fantasy and imagination helps them better identify with and understand the natural world. Allowing children to experience challenges and become things they discover better assists them in connecting to the environment. It enables them to build a sense of place. Finding and fostering special places in these natural habitats helps children better connect to place and leads toward deeper understanding and connectedness to the land.

As professionals in the field create and change children's outdoor play areas, it is important to consider how these spaces are designed. Including many natural elements that foster nature play, challenge emerging abilities, foster building relationships, encourage imagination and creativity, as well as allowing time to engage in exploratory play will help young children experience nature and develop to their full potential. Thoughtful planning, encouragement, and caring will enable young children to develop into tomorrow's healthy and knowledgeable environmental consumers and decision makers.

NEONATAL BEHAVIORAL ASSESSMENT SCALE

For much of the 20th century, neonatal assessment focused on the so-called primitive reflexes and postural reactions, and was intended to identify problems or abnormalities as early as possible in the life cycle. Assessment scales were based on the assumption that the newborn infant was indeed a "blank slate," a reflex organism, operating at a brain-stem level. However, a growing body of research on newborn capabilities in the 1970s led to a greater appreciation of the human newborn as a responsive organism, capable of organized behavior. With the development of the Neonatal Behavioral Assessment Scale (NBAS), the scope of newborn assessment was expanded to include detailed descriptions of infant competencies and the full range of individual differences in newborn behavior. This entry provides an overview of the content of the NBAS, its adoption by researchers, and application as an educational tool.

The Development of the Neonatal Behavioral Assessment Scale

The discovery that newborns could see, hear, and respond differentially to positive and negative stimuli contributed significantly to the development of the NBAS by T. Berry Brazelton and his colleagues in 1973. The NBAS is based on the assumption that newborn infants possess a rich behavioral repertoire of visual, auditory, and perceptual abilities that enables them to explore the world around them. Because it yields

a comprehensive description of newborn behavioral competencies, on the one hand, and identifies individual differences in newborn behavior, on the other, the NBAS can be said to begin where other neurological and behavioral scales left off.

Never conceptualized as an objective assessment in the classic psychometric or medical diagnostic tradition, with an emphasis on pass/fail criteria, the NBAS is based on a broader appreciation of the complexity of newborn behavior. It consists of 28 behavioral items, which measure the infant's behavioral capacities, and 16 reflex items, which measure the infant's neurological status. The scale describes the infant's functioning in seven key areas:

1. *Habituation*—the infant's ability to respond to and inhibit discrete stimuli while asleep
2. *Orientation*—the newborn's ability to attend to visual and auditory stimuli
3. *Motor*—motor performance and the quality of movement and tone
4. *Range of State*—infant arousal and state lability
5. *Regulation of State*—the infant's ability to regulate his or her state in the face of increasing levels of stimulation
6. *Autonomic Stability*—signs of stress related to homeostatic adjustments of the central nervous system
7. *Reflexes*—records the number of normal and abnormal reflexes

The Neonatal Behavioral Assessment Scale's Impact on Research

The NBAS has been employed by researchers over the last four decades to provide a window on newborn and infant abilities. These studies have expanded our understanding of the range of variability in newborn behavior patterns and the effects of a wide range of pre- and perinatal factors on newborn behavior and development.

The NBAS has been used in studies of intrauterine-growth-retarded and premature infants, for example, in studies of the effects of hyperbilirubinemia; different modes of delivery; maternal analgesia; the prenatal ingestion of marijuana, cocaine, alcohol, caffeine, and tobacco; as well as the effects of exposure to environmental polychlorinated biphenyls (PCBs). The NBAS is also used to examine the effects of postpartum depression on newborn behavior and the effects of newborn behavioral differences on the parent-child relationship. Although the NBAS was designed primarily to describe individual differences in newborn behavior, it has been used in longitudinal studies to provide a baseline or starting point against which to measure future change or continuity, as a predictor of developmental outcome.

The NBAS has also been used extensively in cross-cultural studies. This body of research reveals a wide range of variability in newborn behavioral differences across cultures. Furthermore, these studies suggest that whereas the basic organizational processes in infancy may be universal, the range and form of these adaptations are shaped by the demands of each individual culture. In this way, cross-cultural studies using the NBAS have not only confirmed the bidirectional nature of development but expanded our understanding of the range of variability in newborn behavior patterns and the diversity of child-rearing practices and belief systems across settings.

The Neonatal Behavioral Assessment Scale and the Newborn Behavioral Observations System as Educational Tools

The NBAS has also been used as an educational tool. A series of studies, summarized by Nugent (1985) and Nugent and Brazelton (2000), showed that demonstrating the newborn infant's behavioral capacities to parents can serve as a mechanism for helping parents learn about their new infant, thereby strengthening the relationship between parent and child and supporting family adjustment. The Newborn Behavioral Observations (NBO)

comes from the NBAS tradition and was developed by Nugent, Keefer, Minear, Johnson, and Blanchard (2007) as a relationship-building instrument, to sensitize parents to the capacities and individuality of the newborn infant and to foster the relationship between clinicians and parents. The focus, however, is on relationship building rather than on assessment per se, and because it is short and flexible, it can easily be integrated into routine care in hospital, clinic, or home settings. As a result, the NBO is being used increasingly by nurses, doctors, home visitors, and other early intervention professionals to help parents become more aware of their baby's capacities, to reduce postpartum depression and promote the bond between parents and their infants from the very beginning.

The NBAS remains the most comprehensive assessment of newborn behavior available and as such continues to play a major role in expanding an understanding of the phenomenology of newborn behavior among researchers and clinicians alike. As we look toward the future, advances in neuroscience will be enriched by the kind of behavioral observation techniques pioneered by the NBAS, so that combining the NBAS with emerging imaging techniques will undoubtedly allow for more comprehensive exploration of the relationship between brain and newborn behavior and development.

NEONATAL HEALTH AND DEVELOPMENT

The neonatal period refers to the first 4 weeks of life beginning at birth. This is a vulnerable time period for a neonate's health and development. Infant mortality most often occurs during the neonatal period. According to the World Health Organization, internationally, 44% of infant deaths under the age of 5 occur during the first 4 weeks of life. This entry provides insight into neonatal health and development issues, including nutrition, reflexes, and sleeping patterns, and outlines several approaches to neonatal assessment.

Neonatal Health

Infant health during the neonatal period sets the trajectory for all later growth and development. In the moments and days after birth, newborn infants must make the successful transition from the womb to surviving outside of their mother.

This transition includes a bombardment of the senses in which infants must adapt to breathing air into their lungs, regulating their own body temperature, seeing light, hearing non-muffled sounds, smelling their environment, and feeling hunger for the first time.

The most common cause of death during the neonatal period is preterm birth. An infant is considered preterm if born before 37 weeks gestation. In the United States, approximately 12% of infants are born preterm. Preterm infants are at higher risk for mortality if their birth weight is lower than 5.5 pounds and/or if they are born before 34 weeks gestation. There are many causes of preterm birth, but the most common factors include maternal prenatal health, genetic conditions, and multiple births. With new medical technologies, infants who are born prematurely often have a better survival rate than they did even 25 years ago but may still suffer long-term adverse effects, including lung, vision, and cognitive difficulties.

Neonatal Assessments

Due to the vulnerability of the infant during this time period, neonates often undergo several assessments upon birth to determine the status of their health. The most common assessment of this kind is the Apgar score, named for the doctor who developed it in 1953, Virginia Apgar. The Apgar is administered immediately upon birth and is used to help determine the level of medical intervention needed for the newborn infant. It measures appearance (color), pulse (heart rate), grimace (reflex irritability), activity (muscle tone), and respiration (respiratory effort), each on a 3-point scale (0–2). A healthy baby typically receives Apgar scores of 7–10, whereas scores of 3 or below often signify a critical need for medical attention. Additional common newborn assessments include the Dubowitz examination, designed to estimate a newborn infant's gestational age, and the Neonatal Behavioral Assessment Scale, designed to evaluate the infant's reflexes and overall neurological strengths and weaknesses.

Reflexes

Newborn infants are born equipped with neurological reflexes that help them successfully adapt to their new environment. Healthy reflexes are critical to newborns' survival. Basic human reflexes include breathing, blinking, sneezing, and coughing. Unique to newborns, reflexes such as rooting and sucking help ensure that an infant's biological need for nourishment is met. When an infant's cheek or mouth is touched, the infant will turn her head toward the touch and search for a nipple with an open mouth, a reflex known as rooting. Once located, the infant instinctively sucks on the nipple for nourishment. Other reflexes that neonates are born with include the palmar grasp (grasping an item placed in their palm), the Babinski response (the toes spread when the bottom of the foot is stroked), and the Moro reflex (a startle response that includes a tendency to extend the arms and legs widely and then pull them back in toward the body as if to grab on to a caregiver; this often occurs in response to loud sounds and/or sudden bumps when the infant feels unsupported). As neonates develop into infancy, they begin to lose some of these early reflexes.

Sleep and Nutrition

Neonates receive their nutrients through either breast milk or infant formula (most often derived from cow's milk). The American Academy of Pediatrics (AAP) and the World Health Organization (WHO) both recommend breast milk over infant formula whenever possible as the preferred form of nutrients for neonates. Breast milk offers additional health benefits when compared to commercially made infant formula, including providing antibodies that reduce the risk of many diseases and lowering the risk of respiratory infections and ear infections. There is also evidence to suggest that breastfeeding protects against childhood obesity, sudden infant death syndrome (SIDS), allergies, and diabetes as infants develop. During the first few days after birth, breastfed neonates receive colostrum from their mother while her body is producing breast milk. Colostrum is

thicker than breast milk and is high in nutrients and disease-preventing proteins. It helps to protect newborns during their first vulnerable days.

Neonates spend the majority of their time sleeping. Initially this is 16 to 20 hours in a 24-hour period, but the amount of needed sleep gradually decreases as they grow. Sleep of newborns is not organized into day/night cycles. Neonates sleep for periods of 15 minutes to 4 hours around the clock, waking to be fed or have other basic needs met. Typically, young infants do not go longer than 4 hours without needing nourishment and they communicate this need to their caregiver through crying. Individual variations in the feeding, sleep cycles, and crying of neonates are due to a variety of factors including their health, individual temperaments, and caregiving environments. When awake, healthy neonates differentiate their time into several different states including drowsy, quiet alert, active alert, and crying. The quiet alert state is the most optimum for learning and development to occur. In this state, newborns observe their world and take in new information through the use of their senses, making it the optimal time for interactions with caregivers.

NEUROSCIENCE AND EARLY EDUCATION

Neuroscience and early education brings together researchers from several different disciplines, such as neuroscience, educational psychology, educational theorists, and early childhood education, to investigate the importance of brain functioning and education and how they work together. There are windows of opportunity within the brain when optimum learning takes place. It is important for educators of young children to know when and what type of learning should be introduced and taught during these windows of opportunity. By understanding how the brain learns, the information gleaned enhances learning in young children and increases the development of social, emotional, and cognitive development.

Overview

Characteristics that are commonly identified as relevant to early childhood education are any learnings, guided or through discovery, that take place in the earliest part of life, beginning at birth and continuing through third grade. These years support the most basic of needs, including security, social interaction, language acquisition, cognitive functioning, large and small muscle development, and social/emotional skills. These basic functionings are learned as infants and are strengthened to continue successfully through discovery, both guided and unguided, and throughout future learning.

Nature versus nurture can affect the ways that a child learns along with environmental factors, such as poverty or low socioeconomic backgrounds; lack of proper parenting; poor diet; and physical, verbal, or emotional abuse, as well as neglect. These factors can make learning difficult.

The study of neuroscience allows for intervention and remediation in making changes in behavior and in missed learning opportunities to aid the child in recovering from some of these factors. Over the years, researchers have discovered that our experiences shape the way the brain functions. By studying the brain, researchers have learned what is innate and what is learned. This information helps support interventions and helps the brain rewire itself as remediation takes place with learning. It also shows us how to support the missed opportunities to retain information.

Research

Even though information about neuroscience is growing, it is important to remember that it is a new and ever-evolving field. As parents and educators, it is necessary to be sure that the information gleaned is current and reputable. There is much information available that has been proven to be untrue or is out dated. These “neuromyths” can cause more harm than good when it comes to educating young children.

Infant brains produce a trillion more synapses than do adult brains. From birth through around the age of 3, a child’s brain is growing at a very rapid pace. By the age of 3, 90% of a child’s brain has developed (Szalavitz & Perry, 2010). This period is when 50% of all human learning occurs. As the brain is stimulated, brain circuitry is developed and the brain strengthens the synapses. Synapses that are not being sufficiently used will die off. Lack of adequate stimuli during this time can result in abnormal brain development.

Jensen (2005) suggests that children learn material quickly and easily between the ages of 4 and 10. The brain is predisposed to learning. The more opportunities and enriched experiences a child has, the better the results are for building a strong foundation for learning. These complex learning experiences have positive effects that can last a lifetime.

The brain’s ability to change and shape itself is referred to as “plasticity.” This ability allows for it to change and adapt to the environmental stimuli. Each experience a child has can have either a

positive or a negative impact on him. Timely intervention can allow for the brain to recover from potentially damaging effects.

Some of the major research results specific to neuroscience and early childhood include the following:

- Noted brain differences between typical and atypical developing children
- Relationships between brain development and language acquisition in infants and toddlers
- How nature and nurture are intertwined and how this intertwining affects young children
- Influences of early brain development and considerations for early literacy for children who are considered at risk
- How brain development is applied in brain-based education
- Identified brain differences in children diagnosed with autism spectrum disorder when compared to typically developing children
- Ways that information about brain development is related to learning to read
- Information about brain development and twice exceptional (gifted, with a disability) young learners
- Moral and ethical concerns about using neuroscience to teach young children
- Effective strategies for teachers to implement related to brain development

Brain Development

The use of brain imaging technologies such as functional magnetic resonance imaging (fMRI), computerized axial tomography (CAT) scan, position emission tomography (PET) scan, and electroencephalography (EEG) are just a few of the ways that science is able to use brain imaging to have a “window” into the brain. Educators are just beginning to use the information from these technologies to assist them with further understanding of how the brain is stimulated. These procedures were formerly used strictly for medical purposes, but now educational researchers are beginning to use this information to gain more knowledge about the brain’s activity.

The brain is divided into two hemispheres. Each hemisphere is divided into lobes. Each lobe has a specific job to do; but due to the complex nature of the brain, when one lobe is not doing its job another lobe tries to compensate to help to do the job of the other lobe. The four lobes are frontal, parietal, temporal, and occipital. The frontal lobe is responsible for emotions, reasoning, parts of speech, and planning. Creativity, problem solving, and impulse control are also based in the frontal lobe. The parietal lobe has to do with senses and sensory input: taste, touch, pain, pressure, temperature, and spatial relations. The temporal lobe is responsible for hearing, language, and memory and processing auditory stimuli. The occipital lobe includes visual processing, vision, recognizing objects, and perception of light, colors, curve, and lines. Brain development happens differently and at differing times for each of the four lobes.

Interventions

Neuroscience cannot tell us how to care for children, but if the information gleaned from years of research is used wisely it can show us a different way of using intervention to help to provide for the critical periods of learning. Windows of opportunity should be used to teach children for optimal results. In order to do that, one must understand what types of learning should be taking place at each critical period. Being able to begin with what the child knows and building upon this prior knowledge or personal connection allows for optimal retention of information. Best practices should also be used when teaching anyone regardless of abilities. Remediation and intervention can happen at any period and at any age but is the most successful the earlier the potentially damaging effects are identified.

NONCURRICULAR PLAY

In *Being a Boy*, Charles Dudley Warner described recess in late-19th-century New England schools as a shining light in a school culture characterized by discipline and weariness. Children expect to receive a respite from the rigors of the school day in the form of outdoor recess. School recess periods provide children with opportunities to engage in freely chosen activities with their peers and are recognized cross-culturally as an important

component of the school day. In China and Japan, for example, students are offered recess breaks between formal lessons, and in the United Kingdom preschool children are offered periodic breaks from the early childhood classroom. This entry examines the benefits of noncurricular play, including its academic, emotional, social, physical, and creative benefits. This entry also considers why there was a decline in noncurricular play beginning in the 1980s.

Reasons for Optimism

There are reasons to be optimistic about the state of recess in the United States. One positive is the number of government agencies, multidisciplinary associations, and professional organizations championing the importance of recess for whole child development (cognitive, creative, emotional, physical, social) through various statements, policy recommendations, and initiatives. These include the American Academy of Pediatrics (AAP), the Association for Childhood Education International (ACEI), the Centers for Disease Control and Prevention (CDC), the International Council for Children's Play (ICCP), the International Play Association (IPA), the National Recreation and Park Association (NRPA), the National Association of Elementary School Principals (NAESP), the National Association for the Education of Young Children (NAEYC), the Society for Research in Child Development (SRCD), and The Association for the Study of Play (TASP).

In addition to the organizations supporting recess and child-initiated play, empirical research documents its benefits on whole child development as well. Although the recent trend in many schools has been to reduce or eliminate recess in order to increase time for academic preparation and improve academic achievement, empirical research does not support the elimination or reduction of recess for these purposes.

Theories Supporting Recess

Rationales for promoting recess as a vital element of the school day are supported by two complementary

theories. The first is related to the idea of massed versus distributed practice. Distributed practice advocates the distribution of academic learning over an extended period of time. When forced to work continuously without a break, the brain becomes less efficient. Therefore, distributing workload for challenging cognitive tasks has been shown to improve achievement, attention, recall, learning, and productivity.

The second, cognitive immaturity theory, holds that the developing nervous system and lack of life experiences make it difficult for children to perform challenging cognitive tasks as well as adolescence and adults. This holds that children should perform best and be more focused when offered recess or a similar activity break between challenging cognitive tasks.

Benefits of Recess for Whole Child Development

Scientific research holds that recess is a vital component of the school day that offers many benefits for whole child development. In a 2000 report, the CDC defines recess as time offered daily for child-directed physical activity and play. Other common characteristics of recess include that it provides a necessary break from the rigors of the school day; it is the favorite school activity for many children; it occurs daily; it stimulates the senses and invigorates the spirit; it enlivens the soul; it allows children to interact freely and is unstructured in nature; it is child-directed; it often occurs outdoors; it is a child rights and social justice issue; it often lasts 15 to 20 minutes, but it decreases as children age; it is less available to children of low socioeconomic status in urban settings; it is often combined with lunch; and it should be supervised. The following is an examination of the positive outcomes realized when children participate in school recess on a consistent basis.

Academic and Cognitive Benefits. Following a recess break children are more attentive, raise their hands to participate more frequently, and are better able to perform cognitive tasks.

Social Benefits. In 2010, the CDC reported that recess promotes social competence and development in children. The social interactions fostered during recess provide the time necessary to adapt and adjust to the complex school environment.

Emotional Benefits. In a 2009 study, Romina M. Barros, Ellen J. Silver, and Ruth E. K. Stein found healthy friendships to be integral in improving a child's ability to cope with transitions from preschool to elementary school.

Creativity Benefits. A 2007 study by Godwin S. Ashiabi found that schools encouraging pretend play at recess reported children with greater amounts of imaginativeness and enhanced curiosity.

Reasons for Pessimism

Research documents an alarming trend to reduce recess over the past 30 years. Michael M. Patte has found the trend of decreasing time for daily recess and increasing time for academic preparation began in the late 1980s. Others have reported that some 40% of American elementary schools are eliminating or reducing recess time to prepare students for state and national assessments, especially in urban centers with large numbers of children from underrepresented populations. To highlight this, Susan Ohanian has reported that urban schools in Atlanta constructed schools without playgrounds to demonstrate their commitment to high academic standards.

Conclusion

The National Center for Educational Statistics reports that 55 million U.S. students attend public and private elementary and secondary schools each day. During the past 30 years a concerning trend to reduce or eliminate recess from the school day has impacted more and more of these students. Despite this trend, recent theoretical and empirical research suggests that recess plays a vital role in whole child development. Further, research

has indicated that eliminating recess may have negative effects on academic achievement and is associated with many negative outcomes for children.

NUTRITION

Appropriate nutrition is vital to the growth and development of young children. In addition, the importance of eating experiences within early education and care settings cannot be overstated. Educators interact with young children during meal and snack times as children practice fine motor and social skill development, learn about science, and establish healthy habits. This entry examines four concerns that are of great relevance to children in early care settings: (1) nutrient and food needs, (2) the influence of the early care setting, (3) nutrition recommendations, and (4) best nutrition practices.

Key Concepts in Nutrition

In order to explore the importance of nutrition in early care settings, it is helpful to define the key concepts used by nutritionists. Nutrients are constituents of foods needed to sustain life. Foods are nutrient-containing items that are eaten, such as rice or tomatoes. We can group foods into categories: grains, vegetables, fruits, dairy, and protein. Energy intake refers to the consumption of foods and beverages that contain calories. Carbohydrates, fats, and proteins are nutrients that provide energy. Although vitamins and minerals do not provide energy, they are essential for optimal body function. Energy expenditure refers to energy that is spent to sustain life, digest food, support growth, and allow movement. In children, energy balance refers to the balance between energy spent and consumed; this balance results in healthy growth without development of excess body fat.

Developmental Need for Nutrition

Early childhood is a time of substantial growth and development. Thus, the need for high-quality food is crucial. Young children are particularly at risk for iron, calcium, zinc, or vitamin D deficiencies. However, children's total energy needs are substantially lower than those of adults. Since

young children need many nutrients but little energy, each meal should contain an assortment of nutrient-dense foods that provide a lot of nutrition but few calories (e.g., many vegetables, and few energy-dense foods with low nutritional value and high calories, such as candy). Overconsumption of energy-dense foods can lead to the development of overweight and obesity conditions that coexists with nutrient deficiency—this is known as the nutrition paradox.

The Influence of the Early Care Setting

Food preferences are established during early childhood. The greater the variety of foods that children eat at a young age, the more varied the foods they will eat as they get older. Since young children naturally prefer sweet and salty foods that are often low in nutrients, caregivers need to work diligently to provide opportunities to taste and eat nutrient-dense foods. The early care setting has the unique opportunity to complement parents by regularly providing a wide variety of healthy foods from many cultures. Although children who are picky eaters (i.e., children who exhibit signs of food neophobia) have preferences for fewer foods, caregivers can provide repeated exposures (between 8 and 15 times) to increase the acceptability of novel and less favored foods.

The influence of the early care setting is greater than that of just the foods that are provided, since staff, learning experiences, and peers all contribute to foods that are consumed. While teacher modeling alone does not appear to increase intake of fruits and vegetables, modeling coupled with encouraging phrases (e.g., “I love my peas, they are healthy for me”) does increase consumption. Moreover, peers are effective role models, although perhaps more so for girls. Serving appropriate portion sizes can also influence food consumption. Allowing children to serve themselves facilitates appropriate portioning. Influencing children’s consumption of healthy foods also occurs outside of meal times. Active participation in stories about healthy foods and participation in gardening and growing fruits and vegetables increase children’s intake of more nutrient-rich foods.

Food and Nutrition Recommendations

Although food information and recommendations are intended to support caregivers, the volume of information and recommendations can be intimidating and confusing. The United States Department of Agriculture (USDA) supports a meal reimbursement program for low-income children, the Child and Adult Care Food Program (CACFP). The CACFP recommends portion sizes for each food group for children ages 1 to 2 and 3 to 5 years. Portion sizes for young children are about half those recommended for adults. State requirements based on Head Start regulations indicate that children attending part-day care should receive one-third of their nutritional needs at the care center, whereas children attending full-day care should receive one-half to two-thirds of recommended daily requirements.

The Dietary Reference Intake (DRI) states the range of energy and nutrients needed for each life stage. Those grams and micrograms can be challenging for people to interpret and use in their daily lives. Thus, they have been incorporated into the Dietary Guidelines for Americans, developed by the USDA, which focuses on foods, food groups, and key nutrients such as salt. The USDA also developed MyPlate. The plate image, which is divided into five proportional sections, helps people more easily incorporate the USDA’s Dietary Guidelines into their life. Energy intake recommendations range from 1,200 to 1,400 kilocalories for 3-year-old children to 1,200 to 1,600 kilocalories for 4- to 5-year-old children. These recommendations are based on a child’s level of physical activity; as a child becomes more active, more energy intake is needed to achieve energy balance.

Best Practices for Nutrition and Physical Activity

Selected standards for early care settings from the Caring for Our Children: National Health and Safety Performance Standards benchmarks from the Academy of Nutrition and Dietetics position statement are highlighted as follows:

1. Facilities should develop and provide to staff and families a written nutrition plan and menu developed by a qualified nutritionist.
2. Facilities should acquire special nutrition or feeding modification needs.
3. All meals and snacks provided should meet CACFP standards.
4. Healthy, low-fat foods should be offered daily by the facility.
5. High-energy foods with sugar and foods high in sodium should be limited at the facility.
6. Children should be offered food at least every 3 hours and be allowed adequate time to eat.
7. Water should be available, indoors, outdoors, and throughout the day.
8. Facilities should support breastfeeding, with a designated place for nursing or pumping.
9. Infants should be fed by the same caregiver whenever possible, and should be held during feeding; they should not be fed in the crib or propped up.
10. Meals should be served and eaten family style, while caregivers encourage children to eat healthfully and listen to satiety cues.
11. Caregivers should engage in nutrition education with children.
12. Toddlers and preschoolers should be allowed 60 to 90 minutes of outdoor play.
13. Two or more caregiver-led activities should be incorporated throughout the day.
14. Caregivers should promote active play by encouragement and participation.
15. Screen time should be limited.

These benchmark standards are the foundation for early care settings to prevent child obesity and encourage the development of healthy eating habits and behaviors of young children. All facilities are encouraged to develop action plans and work toward achieving these benchmarks.

OBESITY PREVENTION

As of 2012, nearly 23% of children ages 2 to 5 years in the United States were considered overweight or obese. Children who are obese are at risk of serious health issues, including type 2 diabetes in childhood, and heart disease in adolescence and adulthood. This problem is not isolated to the United States, but can be found in all developed countries and many developing countries. Early childhood is clearly the time to begin to address this epidemic.

Factors Contributing to Obesity

There are three general factors that have led to the obesity epidemic:

1. Unhealthy food choices
2. Lack of adequate physical activity
3. Overall lifestyle behaviors, in early childhood programs, the home, and the community

To significantly address childhood obesity, all three areas must be comprehensively targeted. In early childhood programs, healthy food choices, adequate and regular physical activity, and a daily routine that requires physical activity are directly under the control of the program; family and community lifestyle choices are not. However,

programs can impact these areas by working closely with families and communities.

Addressing Poor Food Choices

In early childhood programs, unhealthy food choices include (a) too many salts, sugars, sodas, fruit juices, and other unhealthy foods and ingredients; (b) serving children too much to eat at meal times; (c) using sweet foods as bribes to eat “healthy food”; and (d) providing no access to food between regularly scheduled meals.

Programs need to monitor the foods they introduce, provide healthy options for the children, and work with families to help them understand the reasons healthy food choices are so important. Sugary treats, juices, and sodas should not be used for celebrations, as this creates an association between unhealthy food and having a good time. Children can cook healthy snacks with teachers for celebrations, if need be. Experts suggest children help to prepare foods; further, having a garden within the program (or within a community garden) can help children know where food comes from and how to grow it. The more children are involved in growing and preparing a meal, the better.

Programs can encourage children to serve themselves by providing food and drink in manageable containers. Small utensils, jugs, and other items need to be provided. Children should begin with small amounts of food on their plate; they can always add more, if needed. This develops skills in

portion control and in trying new foods, and children learn to regulate food and caloric intake. Adults should sit with children at the table and eat and drink the same foods as the children. This enables adults to model healthy food choices. Programs that cannot provide family-style meals can at least serve small portions and encourage children to ask for seconds if needed. Children should never be coerced to finish what is on their plate, or told to eat certain foods and then be rewarded with dessert.

Increasing Physical Activity

Young children are naturally active. In fact, some experts believe young children are preprogrammed to engage in certain levels of activity, and to consume enough calories to fuel this activity. When physical activity is reduced, these calories become fat. Thus most physical activity in the program should be unstructured free play, both outside and inside, such as games, climbing on play equipment, balancing, and running. Additionally, dance, gymnastics, simple games, and so on can be taught on a regular basis.

However, two concepts should be kept in mind: (1) the activities must be pleasurable, in order to develop a lifelong disposition toward physical activity, and (2) until ages 7 to 9 (concrete operations period), most organized games should not be taught. In all cases competition should be deemphasized, and children should not stand around watching others play.

Changes in Lifestyle

In early childhood programs, changes can be made to the daily schedule to help children develop a healthy lifestyle. These changes include the following:

- Physical activity occurring throughout the day, and during the teaching and learning of academic subjects (e.g., using physical activity to teach math concepts).
- Healthy food choices made available and modeled throughout the day.

A climate needs to be created where physical activity is viewed as the optimum way to learn, as opposed to passivity and sedentary behavior. This requires a radical shift in how children's behaviors are viewed, and how the day is organized. Children's active, physical, and dynamic movements need to be encouraged; attempts at controlling behavior should focus on safety and the security of others. Active children should never be punished by denying them the opportunity to be active and to play outside. Further, the concept of "appropriate" and "inappropriate" behaviors to label children with attention-deficit/hyperactivity disorder (ADHD) must be seriously challenged. Adjustments can be made to the environment and curriculum prior to a diagnosis of ADHD or another disability to see whether these changes can modify the child's behavior. Young children—especially boys—are naturally active, spontaneous, and have short attention spans. Increased academic expectations often pressure teachers to have inappropriate expectations of young children. Frequent physical activities, kinesthetic learning opportunities, and ongoing outdoor experiences work well with these children. Teachers should not use a disability label, such as ADHD, for any child who has not been formally diagnosed; once diagnosed, these labels should still not be used in public discourse around parents and other children.

Encouraging healthy food choices in early childhood programs means providing lots of vegetables and fruits, and the opportunity to snack on vegetables and fruits between meals. One reason some children overeat—particularly children from poor countries or those who do not get enough to eat at home—is because they do not know when the next meal will come; they need to know they can snack between meals.

Challenges in Modifying Early Childhood Programs

Challenges in modifying early childhood programs to address childhood obesity include budget priorities that focus on technology and traditional learning materials, rather than challenging and safe playgrounds and indoor environments that

encourage gross motor activities; a focus in staff training on pre-academic skills (such as learning letters and numbers) and discipline; and early childhood education standards that focus on development of academics and on teaching adult-expected behaviors. In developing early childhood policy, consideration should be given to providing funding for equipment that helps children be active, training staff to encourage healthy food choices and physical activity, and changes in standards to emphasize physical activity and the arts in the early years.

Working With Families and Communities

The focus of this entry is on how early childhood programs can impact childhood obesity. However, families and communities have an important role to play in addressing the obesity epidemic. Early childhood programs can be a good role model, communicate to families, and engage the community in a variety of activities to enhance a healthy lifestyle. Most urban communities have a variety of community gardens and farmers markets, and many playgrounds, parks, trails, greenways, and sports venues that can be accessed by families to provide a healthy lifestyle for their children.

OBJECTIVITY AND SUBJECTIVITY IN ASSESSMENT

Objectivity and subjectivity in assessment refers to the nature of data gathered through an assessment process. Objectivity defines information that is collected through measuring, observing, and examining facts. Subjectivity describes information that is based on personal views, opinion, or value judgments. Some researchers view objectivity and subjectivity as opposites, while others suggest that they are at either end of a continuum. All assessments fall somewhere on this range. Typical assessments in early childhood include observational assessments, analysis of children's work, developmental screenings, and standardized tests, to name a few. Every assessment will have some characteristic of objectivity and subjectivity. This entry describes both objectivity and subjectivity and the relationship of this continuum to assessments in early childhood education.

Objectivity

Objectivity is the ability to see things without being influenced by personal feelings, emotions, or judgments. An objective assessment is based on evidence or facts. Assessments that are considered objective have a right and wrong answer that will be evaluated in the same way for every person assessed. Multiple-choice questions, true/false items, or matching activities are categorized as objective.

In early childhood classrooms, observational assessments and analyses of children's work are to be collected with objectivity. Anecdotal records,

running records, or captions on work samples are to be written without judgment to describe only what is observed. Standardized tests are also characterized as objective because they are administered and scored with the same protocol for every individual. Some assessment tools used in early childhood are created with objectivity, but require some element of subjective interpretation.

Subjectivity

Subjectivity is the personal interpretation of a situation and is usually based on feelings or opinions rather than facts. Collection of information about a child's development, skills, or knowledge can be influenced by the personal relationship a teacher has with an individual child. Similar behavior (saying "no!" to a request) exhibited by two different children can be interpreted subjectively (as "defiant" or "courageous" or "self-assured"). The choice of evaluation methods can also be guided by an individual's experience, feelings, and biases.

The very foundation of the work of early childhood professionals is guided by subjectivity. Building relationships is subjective work, based on feelings, intuition, and perception. The continuum of objectivity and subjectivity in assessment is a critical aspect to be considered.

Objectivity and Subjectivity in Early Childhood Assessment

The early years in a child's life are marked by great variability and change. Development is not a smooth process. Rather, a child's physical, social, emotional, moral, cognitive, and language development is characteristically uneven, with starts and stops that can influence the outcomes of any assessment. These inconsistencies underscore the delicate nature of assessing young children.

Because young children do not have the capacity to perform accurately on paper-and-pencil tests, evaluation of what a young child knows and can do relies heavily on the individual completing the assessment. The person administering the assessment brings his or her own biases, usually unknowingly, to

the experience. These prejudices can influence how the outcomes of the assessment are perceived, recorded, interpreted, or documented.

Reliability and validity are two key characteristics of early childhood assessments. Reliability describes the consistency of an assessment tool and how it measures when repeated time after time. Reliability can be affected by external factors such as the testing environment or scorer of the test. It can also be shifted by the aspects of a child's disposition: wakefulness, attention, or hunger. The younger the child, the more dramatic these effects may be.

Validity describes how well an assessment measures what it is intended to measure. Determining if an assessment has validity is the first step in determining if the information gathered will be useful. When an assessment tool is created, its validity is established by how it is designed and how the purpose is defined.

Objective assessments are not immune from subjectivity. The individuals or groups creating or writing the assessment bring their personal, professional, and cultural backgrounds to that experience. This may unintentionally impact the assessment, especially if a child is an English language learner or has some impairment. To ensure that the most accurate and appropriate decisions are made about children and about programs, early childhood educators must become aware of their subjectivity when administering or interpreting assessment results.

OBSERVATIONAL ASSESSMENT

Internationally, assessment of young children is an increasingly important topic, as many governments become concerned about their investment in early childhood education and seek evidence on outcomes of investment. One example is Head Start in the United States, a program that is federally funded to ensure that children growing up in poverty receive high-quality early childhood education and are prepared to start school. This is the policy initiative developed to close the gap of economic disadvantage. Significant focus has fallen on validating scientifically based assessment that will demonstrate requisite Head Start program outcomes have been achieved and that children are making progress across the range of developmental domains.

One assessment measure is the Preschool Child Observation Record, Second Edition (COR-2), a widely used early childhood assessment of multiple domains that are important for school readiness, although implementation has been found to be problematic, according to Katherine M. Barghaus and John W. Fantuzzo. Alice Bradbury argues that the use of formal assessment systems with young children is unusual, but use in the United Kingdom with 5-year-olds is consistent with an emphasis on accountability and the “high stakes” assessment systems used in compulsory schooling. Bradbury proposes that a focus on measures of attainment must be tempered with awareness of the complexity of the relationship between assessment and

inequality, particularly in relation to teacher judgments, that are subjective assessments.

The focus on psychometric assessment methods is arguably not as strong in other developed countries as in the United States, but there are signs that such a focus is increasing internationally. Work by the Organisation for Economic Co-operation and Development, reported by Rowena Phair, on designing an outcomes assessment tool that could be used internationally to provide comparative data is evidence of this focus. However, this entry does not focus on the suitability of psychometric assessments to test early childhood education outcomes or on research that examines how quality of early childhood education can be measured using standardized observation; instead, issues of how teachers can use observational assessment for the purposes of formative, summative, and ipsative assessment of young children are explored.

Formative, Summative, and Ipsative Assessment

Renée M. Casbergue cautions, “Belief that assessment is the source of multiple ills in classrooms for young children may lead some teachers to eschew calls for documenting children’s learning and development” (2010/2011, p. 16), but suggests that teachers need to understand the purpose of a range of assessment tools and make wise use of them. She further proposes teachers need to understand the difference between formative and summative assessment. Formative assessment of learning is applied as learning is occurring and is used to guide future learning. Summative assessment provides a summary of achievement at the end of a unit or period of learning. Ipsative assessment involves assessing children’s learning against their own performance, to determine if progress has been made. In the early childhood context, assessment typically uses all three methods, although they may not be identified as such, according to Claire McLachlan, Susan Edwards, Valerie Margrain, and Karen McLean.

The notion of assessment *for*, *of*, and *as* learning is also useful, suggests New Zealand’s Ministry of Education. Assessment *for* learning occurs when

teachers use inferences about children's progress to inform their teaching. Assessment *of* learning occurs when teachers use evidence of children's learning to make judgments about achievement against goals and standards. Assessment *as* learning occurs when children reflect on and monitor their own progress to inform their future learning goals. In the New Zealand context, observation is the only named assessment tool in the early childhood curriculum. Although other countries may not be so explicit about its importance as an assessment tool, it is still a heavily relied upon method of understanding children's learning and development and thus needs to be used well. Effective use of observation is particularly important in contexts where narrative observational assessment methods, such as New Zealand's "Learning Stories," are used.

Use of Observation for Assessment Purposes

There are some common features of observation as an assessment method. These include the following:

- *Direct observation.* It relies directly on what the teacher can see.
- *Fieldwork.* It relies on the ability of the teacher to search directly for information rather than relying on secondary sources.
- *Natural settings.* This method relies on gathering data as they happen, rather than in stimulating behavior or simulating real-life conditions, such as laboratory research. However, a major concern is to avoid disrupting normal behavior; minimizing observer presence is an issue.
- *The issue of perception.* The observer is never neutral and teachers' perceptions of situations can be influenced by personal factors; thus, data collected can be unreliable. It is possible to reduce unreliability, but it is a limitation of the method.

Simon Warren suggests it is impossible to separate interpretation from observation: "what is 'seen' then, is not the real, in the sense of an experience distinct from interpretation"; he argues that "reality is always a moving target, always in the

process of becoming, always already interpreted" (2000, p. 132). Lev Vygotsky made a similar point, arguing that development is always in a state of change—not static and ready to be captured—and as such it is difficult to make judgments about children's learning. Furthermore, Vygotsky's theory has informed research into assessment of children because it shifts the focus from the individual child to what and how children are learning through social interaction within a given context.

It is also useful to consider quantum mechanics and Werner Heisenberg's uncertainty principle when undertaking observation: the act of observing something changes its nature, sometimes called the "observer effect." Apart from the effect of observations on children's behavior, teachers can never be certain that their perception or interpretations of what they see is "real." As part of overcoming the reliability difficulties of assessing young children, Stephen J. Bagnato argues that methods should be "authentic"—that is, based on what children know and can do, use materials that are familiar to the child, be connected to children's learning in other contexts, and use multiple sources of information to capture children's learning at different times or during different activities.

Observation is shaped by perception, including memory, past experience, and the current situation. In terms of memory, people forget most of what they see, but according to Elizabeth Styles there is a pattern to what they recall and it is not random. This is called *selective recall*. Also, the mind filters information, allowing some to pass through and putting up barriers to others, enabling selective perception of "what happened." Finally, perceptions are shaped by teachers' emotional and physical state, so what teachers observe is shaped by current emotions. Thus, being hungry, tired, angry, frustrated, or prejudiced produces *accentuated perception*. Teachers also use a range of filters to help them cope with the perceptual demands of observation, according to Martyn Denscombe:

- *Familiarity.* Teachers tend to see what they are used to seeing. If the situation is ambiguous, it is usually interpreted in terms of past experiences.

- *Past experiences.* Past experience causes teachers to filter out certain “nasty” stimuli or to exaggerate desirable things.
- *Current state.* Physical and emotional states and current priorities can also alter perceptions.

Thus, being healthy, rested, and positive when teachers observe children is ideal, as well as is recognizing the filters that teachers may use to interpret observations, states Bradbury.

Worldviews of Childhood and Observation

Edwards states that many models of observation for young children are based on deficit notions of child development, in which teachers make comparisons of individual children against universal stage theories of child development. Furthermore, recent “postdevelopmental” thinking about childhood, drawing on sociology, poststructuralism, and postmodernism, challenges the idea that children’s learning occurs in separate domains and occurs at particular ages and stages, according to Andrea Nolan and Anna Kilderry. Although many teachers value the broad parameters developmental theories provide for assessing children’s learning, most are inadequate for explaining development of children from diverse cultures. A postdevelopmental perspective suggests teachers view children’s learning as part of their “being” in the moment, rather than what they are “becoming,” emphasizing multiple ways of thinking about children and childhood. Rather than conceptualizing one “true” way to understand how children learn and develop, teachers need to understand children’s families and communities and draw on local representations of how children learn and develop.

To understand the complexities of children’s learning, teachers need to engage in regular observation so they can identify children’s strengths, interests, preferences, and needs—assessment of learning difficulty being a child’s right in order to gain access to further support. Teachers can identify, through regular observation and reflection,

key areas in which they need to support children to learn and develop.

Types of Observation

Denscombe argues that there are essentially only two types of observation:

1. *Systematic observation:* Methods that fall into this category typically gather quantitative data and involve the use of statistical analysis.
2. *Participant or nonparticipant observation:* Typically methods used produce qualitative data and usually involve teachers observing children as they work with them.

There is a range of commonly used observation methods, which include the following:

- *Structured observations*—a predetermined checklist of things to observe.
- *Anecdotal or instantaneous sampling*—observing something that teachers think should be observed.
- *Event sampling*—a particular event is observed (e.g., settling routines for new children).
- *Critical incident sampling*—observations of the setting and context of a particular regular occurrence (e.g., a child biting).
- *Time sampling or interval recording*—observations at predetermined time intervals or where a regular interval of observation is undertaken (e.g., to examine use of a new play corner).
- *Rating scales*—an environment is observed against a set of predetermined criteria on a scale (e.g., Early Childhood Environment Rating Scale–Revised [ECERS-R], Harms, Clifford, & Cryer, 1998, to review center quality).

Barbara Rogoff proposed that observations and interpretations can be framed through three lenses:

- Personal (the child on its own);
- Interpersonal (the child in relation to others); and
- Contextual and institutional (features of the environment in which the child is learning).

It can be useful to frame observations using a three-dimensional or multifaceted approach, as this yields greater information about the child in context. Casbergue calls this “situated assessment” in which teachers capture learning in the context of everyday activities. Items to observe include the following:

- The physical setting—environment and organization
- The human setting—the people and their composition
- The interactional setting—types of interaction taking place
- The program setting—resources, organization, pedagogic styles, and curriculum

Assessment of children’s learning and development in such a way yields richer information that can be used for individual assessment and curriculum planning.

Issues and Challenges of Observation

A number of issues need to be considered in observational assessment. The first issue is *purpose*: Are teachers observing an individual child or a group of children? Teachers need to answer a range of questions that the decision to observe highlights: who, what, why, when, how, and where am I observing? The second issue is *location*. Observers need to have a clear view and to easily hear what is being said by the child or children. If observing in a large area, it is useful to divide the space into areas or enlist help with observations. If another observer is used, prepare a record sheet, so both observers are looking for the same things. The third issue is *timing*: Teachers need to ensure that there is enough time in center routines to gather sufficient observation data; it is also important to decide how many observations are needed. *Preparation* is important: A planned record sheet, which includes time, location, data, observer, area, behaviors, or events, and any other contexts or purposes of the observation, is valuable as part of collecting assessment data.

It can also be useful to video-record or audio-record, but this introduces another element of “observer effect,” states Denscombe. To observe learning and development over time, it is important to plan how often observations will be collected and how they will be used. Sally Featherstone argues that centers should have long-, medium-, and short-term plans for gathering assessment data, including observations, so that systematic collection of data is made possible and is integrally linked to curriculum planning, according to McLachlan, Marilyn Fleeer, and Edwards.

Observation is a powerful assessment tool, but comes with a set of caveats around how far teachers can trust what they have seen with their own eyes. Teachers need to remember that everything they see is an interpretation and not “the truth”; other measures are required to ensure reliability. Observation is more useful if it is done over time with the same child or group of children so more “authentic,” states Bagnato, assessment data can be collected. Observation is a fundamental assessment tool in early childhood settings. Used carefully and with understanding of its limitations, it can be a powerful tool to have in a teacher’s assessment toolkit.

ORAL LANGUAGE DEVELOPMENT

Expression through oral language is one of the toddler's and older child's most remarkable accomplishments. Although talking is often considered a natural phenomenon, learning to talk requires time and proper brain development, along with practice in the child's everyday situations. Because language provides the foundation for all later literacy learning, an understanding of the ages and stages of oral language acquisition is critically important. Equally essential is the caregiver's knowledge of the strategies that adults and peers can enlist to facilitate the child's language development. This entry addresses ages and stages, as well as several recommended strategies, for eliciting optimal oral language development.

Ages and Stages of Oral Language Development

Oral language is used to explore, communicate, ask and answer questions, problem solve, hold conversations, form friendships, and learn about the self, others, and the world. From birth until age 5, the child's development progresses more rapidly than at any other phase in the life span. According to researchers Jill and Peter de Villiers, the infant and child progress through several stages of language development. These stages seem universal and are considered largely innate, since they develop at predictable ages and stages among infants and children throughout the world. The physical development of the brain is largely coordinated with, and responsible for, many components of the infant's and child's language development.

However, the paramount role of nature notwithstanding, one cannot dispute the role of nurture in the development of the child's oral language. For example, John Bowlby, a researcher who studied mother–infant attachment, has found that infants provide many clues to their mothers to signify their willingness to engage in primitive conversations. Infants convey their specific needs and desires through body language and the use of gestures, cooing, facial expressions, crying, smiling, and gurgling. In turn, their caregivers respond with smiles, attention, cuddling, feeding, and simple “conversations” with their infants. This consistent type of caregiver–infant communication supplies the infant with the trial-and-error practice that facilitates socialization, oral language, and later conversations with others.

The following specific ages and stages of language development draw upon works by the New York University Child Study Center and Beverly Otto, and provide general norms for infancy through Grade 5. Caregivers and teachers of young children who become familiar with these stages are able to play, converse, and plan daily activities according to infants' and children's language development levels and their related needs.

6 Weeks: Cooing. The infant attracts attention of caregivers, family, and friends by cooing. Beginning with vowel sounds, the infant uses its tongue, mouth, lips, and open mouth and throat to form sounds including /aaal/ (as in apple), /ooool/ (as in ostrich), /ahhhhl/, /ohl/, and /ohl/. For the new language learner, vowels precede consonants because consonants require a more sophisticated type of articulation.

4 to 6 Months: Babbling. At 4 to 6 months of age, the infant combines consonant and vowel sounds through babbling. For example, the infant makes repeated sounds using the same consonant–vowel combination, such as *ba-ba-ba* or *da-da-da* or *na-na*. This early babbling usually does not yet represent real words; however, when caregivers repeat the babbling with the infant, they encourage infants to continue to experiment with

the sounds and provide language role modeling for them.

8 to 10 Months: Echolalic Babbling. This type of babbling is so named because it reflects and repeats the speech rhythms and intonations of the adults in the child's environment. For example, the adult says, “NICE, dog,” and the infant repeats, “NI-noh.”

1 Year: One-Word Stage. The infant's eagerly awaited first words most often appear at around 1 year of age. The child may call his father “*Da-Da*” or his mother “*Muh-Muh*.” Language becomes more stable at this one-word stage. The infant may use a special sound or word to consistently refer to the same object or person, such as calling a blanket “*ba-ba*.” The family cat might be “*ca-ca*.” A vocabulary of approximately three or four clearly spoken words develops now.

2 to 3 Years: Telegraphic Stage. The child's vocabulary rapidly expands to approximately 300 spoken words. “*Go bye-bye*,” “*Mommy, NO*,” and “*Bad kitty*” are examples of simple combined words typical of toddlers in the telegraphic stage of development. As children string words together, they begin to form the foundation for more complex sentences. The beginnings of *syntax*, the ordering and combining of words to make sense in a sentence, appears at this stage. The child refers to self by name and begins to ask many questions now, such as “*What's that noise?*” and “*Where's Daddy?*” The child's identification of common actions (*run, sing, climb*) and the labeling of body parts are common now, as is the child's ability to name word opposites such as *good–bad, up–down, and big–little*. The young child enjoys listening to short stories and identifies characters and objects in the storybook.

3 Years: Interactive Stage. Language expresses basic needs and feelings through the rapidly expanding spoken vocabulary. The child speaks in three- to four-word sentences, and an understanding of grammar surfaces. Oral language becomes a key that enables the child to interact with others in many diverse ways. Now the child may add to your

comments, answer your questions coherently, tell you about his or her plans, relate observations, recite simple poems, sing short songs, tell you a story, count from 1 to 10 or higher, and name several colors. The child asks many questions now and produces more advanced sounds easily, including /m/, /p/, /t/, /d/, and /w/.

4 to 5 Years: Connected Sentences Stage. Children at this stage of development enjoy dramatizing stories they have heard or seen, such as *Goldilocks and the Three Bears* and *The Three Little Pigs*. The singing voice becomes more in tune, and children can now recite and sing the alphabet with relative ease. They enjoy sharing ideas, silly jokes, plays on words, and short rhymes. The child clearly answers questions and follows a series of three commands with an unrelated theme, such as “*Get the milk, close the front door, and put on your hat.*” The child sustains attention to a story for 20 minutes or longer and recalls its four- to six-part sequence. The child speaks in four- to five-word sentences.

Age 5: Pragmatics Stage. The child at age 5 begins to use more variety in speech and the use of *prosody*—the rhythm, stress, and intonation of speech—improve.

Use of plurals and tenses become correct. The child enlists *semantics*, the ability to combine sounds (*morphemes*), to denote meaning to a word. For example, the child adds an “s” to the end of sock to pronounce the word “*socks.*” The child is able to produce rhyming words, such as *bake* and *cake*. The child can now identify the number of syllables (or claps) in a word, isolate one sound from another, and discriminate between various sounds. These skills demonstrate *phonemic awareness*, the awareness of sound structures of words, which plays a key role in the child’s readiness for reading, according to research published by the National Reading Panel.

Strategies for Promoting Oral Language

Although children’s language development follows several predictable stages, as discussed in the previous

section, specific rates of language development and language usage are as unique as individual children. As adults attempt to scaffold children’s language development, they may enlist the following strategies to promote motivation and readiness for optimal language development, including expression, vocabulary, comprehension, prosody, and communication. Strategies for children with special needs are embedded within the following suggested strategies; however, the advice of a specialist is needed if the child is unresponsive, is overly difficult to understand for his or her age, or seems unmotivated to talk.

- Focus on the positive, and not the weaker, aspects of the child’s language. Allow language to develop naturally, and barring any obvious problems, at the child’s own pace.
- Enlist shared reading, in which the child participates in reading oversized books with the adult. These colorful books often contain chants or rhymes, promoting motivation, phonological awareness, confidence, expression, articulation, vocabulary, and comprehension.
- Read every day. As children hear oral language spoken, they learn the cadence, or rhythm, of language along with expression and new vocabulary words as well as new concepts and develop comprehension skills. Recommended books include poetry, alphabet, songs, pop-up, animal, picture, and fairy/folk tales.
- Use dramatic role play of stories. Supply dress-up props and objects to facilitate the role play. Include, for example, pirate, astronaut, ballet, and wait staff costumes.
- Encourage sociodramatic play so that children have opportunities to reenact their own life situations, such as a visit to the dentist, the first day of preschool, or a family vacation. Sociodramatic play enables children to use their imaginations and creativity as they engage in pretend play about a familiar life topic.
- Treat children as communicators. Hold frequent conversations with them. Take turns with them while listening and contributing to the conversation.

- Introduce “grand conversations” that allow children to learn ideas and language from each other while exploring a topic of mutual interest. The teacher may facilitate the group or dyad discussion but plays a relatively minor role in the course of the conversation.

- Elaborate on children’s contributions. When the teacher enlists a technique called “elaboration,” as defined by Harvard University scholar Courtney Cazden, he or she expands upon the child’s contributions. The child, in turn, acquires a valuable means of supplementing his or her utterances. For example, during a science lesson, a child contributes, “My group found a big rock.” The teacher replies, “Wow, your group’s red rock *is* large and solid!”

- Allow plenty of time for play, including dress-up, free, and parallel play, in the classroom and home. Language develops naturally when children are provided the freedom to explore words and ideas in relaxed settings. Provide play materials and centers including building blocks, carpentry stations, castles, gas stations, and open-ended art supplies.

- Recognize the benefits of storytelling for comprehension and vocabulary development. Storytelling is particularly beneficial for English language learners (ELLs) and children with special needs because the child is free to participate in the storytelling without the fear of embarrassment. In their work, Susan Trostle Brand and Jeanne Donato describe storytelling methods that promote oral language, including draw talk, character imagery, puppetry, chant, felt board, pantomime, and group role play.

- Keep learning and learners active and participatory. Encourage problem solving, experimentation, exploration, outdoor learning, inquiry-based teaching, and discovery. Minimize adult talk and, instead, maximize children’s group work and interactions that include their conversations and sharing of concepts and ideas.

Conclusion

From cooing to babbling, progressing through the later stages, and finally holding adult-like conversations, children’s language development, from

simple to complex, is a fascinating phenomenon. Children use trial-and-error to acquire language, following language usage rules that they observe in others, and experimenting to find their own paths. Adults facilitate oral language development through an awareness of the universal stages of language development, an understanding of each child’s uniqueness, and a working knowledge of best-practice strategies. They lay a strong foundation for the individual’s acquisition and use of oral language throughout the life span.

OUNCE OF PREVENTION FUND

Since 1982, the Ounce of Prevention Fund has been a national leader in improving the quality of early childhood education, which evidence shows increases the likelihood that young children—particularly those born into poverty—will experience positive life outcomes into adulthood.

Rooted in science about brain development, school readiness, the academic achievement gap, and the effects of early life experiences, the Ounce has over time grown its identity as a thought leader in early learning through its programmatic and policy work, research, and professional development.

Programming

In 2000, the Ounce opened Educare Chicago on the city's South Side. The birth-to-5 school served as Illinois's first model for high-quality early childhood education, applying well-supported research and evidence-based practices to inform the education and care that is influential in supporting the healthy development of children at risk of school failure. Independent research has shown that the Educare model helps students enter kindergarten close to the national average in vocabulary, social-emotional skills, and other indicators of school readiness.

In 2003, the Ounce partnered with the Buffett Early Childhood Fund to build a network of high-quality schools using the Educare model in states across the country. Since its inception, the Educare Learning Network has grown to more than 21 schools, delivering high-quality early education to as many as 200 students, birth to 5, at each school.

Policy

By collaborating with state advocacy partners to forge and advance a comprehensive, high-quality birth-to-5 system that includes center- and school-based early learning, as well as evidence-based family support programming, the Ounce has elevated Illinois as a state leader in early childhood education.

Its advocacy efforts have helped drive public support for high-quality early education and helped secure \$52.2 million in Race to the Top—Early Learning Challenge grant funding from the U.S. Department of Education to advance Illinois's early childhood system. At the federal level, the organization has helped secure more than \$650 million in early education funding.

In an effort to strengthen and maintain the gains achieved when young children are provided high-quality early childhood education, the Ounce expanded its work to support the alignment of school districts nationwide with early learning systems. Backed by evidence, the organization insists that the outcomes produced through quality early learning experiences cannot be effectively maintained without the needed support of school improvement plans that are inclusive of early childhood.

Research

Motivated to help improve the trajectory of young children and families through early childhood education, the Ounce has, through its research work, been a leader in the field of early learning. By continuously evaluating its methods and their effectiveness, the Ounce of Prevention Fund has continued to improve its practice of delivering and supporting high-quality early childhood education and sharing its findings to raise the quality of services delivered to at-risk children and families in Illinois and across the country.

The Ounce's ongoing study of its Educare model, for example, continues to inform the field of early childhood education with best practices and subsequently to build support among the public, private organizations, and policy makers for high-quality early learning. Results from the longitudinal study show that children who attend Educare schools arrive at elementary school not just more academically ready, but socially and emotionally prepared, as well.

In addition, the Ounce has engaged in innovation to increase the breadth of the high-quality early learning it promotes. Through the Early Math Initiative at Educare Chicago, the school's children are provided early experiences with

numeracy and problem solving. Early math activities have included cooking, shopping, and gardening—everyday ways in which parents can enhance their child's math skills.

Professional Development

Using its deep and diverse expertise in the field of early learning, the Ounce has also striven to improve the quality of early childhood education and care through the professional development of early childhood teachers, leaders, and providers. The organization has provided professional development to more than 2,500 community-based early childhood professionals, including 950 professionals working in Educare schools across the country. In the state of Illinois, the organization reaches about 90% of family support staff through its home visiting and doula professional development programs. By training at least 3,000 early childhood professionals across the state, the Ounce has served an estimated 11,500 families.

As part of its principal mission to ensure that all at-risk American children from birth to 5 years old have access to high-quality early childhood education, the Ounce, with the help of both public and private funding, expanded its efforts to broaden its reach of early learning professionals. The Ounce has applied its more than 30 years of expertise in home visiting to offer a comprehensive online professional development program. The online accessibility allows for nationwide reach.

Impact

The Ounce has persistently pursued the goal that all children have quality early childhood experiences in the crucial first 5 years of life to build strong individuals, stronger communities, and a strong nation. Studies show investing in high-quality early childhood programs yields a \$7 to \$10 rate of return for every \$1 invested. Further, evidence shows that participation in early learning increases high school graduation and college rates, reduces teen pregnancies, lowers crime and

delinquency rates, and raises adult employment and prospects for a living wage.

OUNCE SCALE, THE

Assessment is an integral part of instruction in early childhood special education (ECSE). The assessment data gathered are required to communicate children's progress, and to determine what children know and can do, individually and/or collectively, at any point in time, before, during, or after instruction. The Ounce Scale is an assessment tool used in some ECSE programs for ongoing, observational, functional assessment of children from birth through 42 months. The Ounce Scale uses Observation Records completed by both parents and early childhood professionals to document progress over time.

Overview of the Ounce Scale

The Ounce Scale is an authentic assessment tool designed to meet several purposes, including but not limited to the following: to document and evaluate child growth and development over time, to provide structure for families and professionals to become better observers of their children, and to enhance child development by increasing family engagement in young children's growth and learning. It is organized around eight age levels and deals with six areas of development: (1) personal connections, in particular how children show trust; (2) children's feelings about themselves, in particular how they express their identity; (3) relationships

with other children, that is, how they act around and respond to other children; (4) understanding and communicating; (5) exploration and problem solving; and (6) movement and coordination.

The Ounce Scale has three main components: the Observation Record, used to document children's everyday behavior and provide data for evaluations about children's development; the Family Album, which provides a way for parents to learn about their child's development as they record their observations, collect photos, and respond to questions; and the Developmental Profile, which enables caregivers and others working with children to evaluate each child's development and progress over time, comparing their observation data to specific performance standards.

Significance of the Ounce Scale

Assessment data is used in ECSE for the development and selection of intervention materials that bring about optimal gains in young children's learning. Effective intervention does not end in the classroom, however; it includes children's natural environments such as the home, community playgrounds, grocery store, park, and library. Therefore, meaningful intervention assessment data will involve parents in the assessment process.

The Ounce Scale meets the standards of effective assessments in ECSE that encourage the involvement of parents, use of multiple data sources, use of developmentally appropriate tools, and use of ongoing performance or authentic assessments (tied to daily activities) to track young children's development and their strengths, progress, and needs over time. Developmentally appropriate practices for children from birth to 8 years old make a case for assessments that are inclusive of parents because they are the first teachers, and they typically know their children better than any caregiver or professional. Involving parents in the assessment process ensures the continuation of intervention methods and curriculum to all natural environments where children with disabilities live, play, and participate.

Considering the important role that parents play in the ongoing assessment process, teachers

and caregivers need to work closely with parents. Literature that sheds light on parental involvement in the Ounce Scale assessment process is still limited. There is a need to understand the barriers to parental involvement in the assessment process that lead to ineffective intervention for children with disabilities. The following section gives a brief report on the findings of a qualitative study that explored early childhood special education teachers' views of the benefits of parental involvement in the Ounce Scale assessment process. Challenges that hinder collaboration between parents and teachers during the assessment process were identified. Specifically, the study sought to reveal benefits and the challenges that infant/toddler teachers experience working with parents during the assessment process. The specific research questions the study sought to address include these: How do early childhood special education teachers perceive the benefits of parental involvement in the assessment process? What barriers do teachers face in working with parents in the assessment process? What are possible solutions to the barriers?

Benefits of Involving Parents in the Assessment Process

All teachers who participated in the study agreed that it is important to involve parents in the assessment process because they know their child better than anyone else. Some teachers who had children with significant disabilities noted that they needed parents to be part of the assessment to ensure the continuation of intervention beyond what they could offer in the classroom to include all natural environments.

Teachers also noted that parents benefit more from gathering assessment information on their children. During the observations, parents focus on their child, and they increase their understanding of their child's development, strengths, and needs. One teacher commented that a parent, once she had written down her observations about her child, found herself surprised at how much her child was able to accomplish.

Challenges Teachers Face in Working With Parents

Most teachers working with families in the Ounce Scale assessment process indicated that one of the major challenges was the lack of child development knowledge on the part of parents. Although the Ounce Scale clearly described the different aspects of development that parents should document on the Observation Record and what to include in the Family Album, oftentimes the data provided by parents lacked clarity, such as giving the date on which a photo showing a particular behavior was taken. From the teachers' comments one can infer the need to train parents about the assessment process, and how the Family Album is crucial as a tool to document progress, and where the child still needs assistance. Some parents did not understand the Family Album was meant to comprise more than photos, and that even scrap writing, or short notes written at the time of the child's behavior, could help explain what the child is able to do.

Some parents are not aware that they are supposed to also provide intervention for their child. As a result, the idea of the Observation Record and Family Album to document needs and progress did not make much sense to them. Parents' experiences of school and beliefs about their role in relation to professionals affect how they take part in the assessment process. If they believe it is the duty of the professional to assess their child, they find no urgency in completing their role.

Possible Solutions

One of the major reasons parents do not contribute in the assessment is the feeling that their observation or input does not matter, especially if they never see their ideas included in the discussion about their child. Professionals need to show that parent observations and evaluation of their child's development matters. Coming up with a visual matrix that compares the caregiver's and parent's observations helps parents with confidence and trust in the assessment process. Table 1 has a simple matrix that could help parents.

Discrepancies in ratings between parents and caregivers open up a rich discussion about the number of times the child was observed by each observer, the environments where the child was observed, what the child is really able to do, and what the child should be doing as the way forward. Information collected in a matrix like that shown in Table 1 may serve as a starting point to discuss the child's needs. Additional information, such as notes and photos from the Family Album, could be used to support what is in the matrix.

In addition to working with families to complete a developmental profile, there is a need to have a discussion with families about effective observation and documentation of what they see. It is important to note that not all information observed will matter; parents need to know exactly what they need to document. In order to get parents to understand that, there is a need for intentional discussions between the parents and professionals. Some of the questions that may guide the discussion include, but are not limited to, the following:

What information do parents need to collect?

How should they gather the information? How much information do they need per week/per month?

What are they learning about their child?

How do they use the information?

In addition, when training parents, one needs to take the *coaching approach*. A coaching approach requires that the practitioner or teacher as a coach provides support to the parents to improve their child's skills and abilities rather than the practitioner working directly with the child.

For parents who may not have continuous access to cameras, there is a need to encourage scrap writing. Scrap writing is similar to anecdotal writing; the difference is that scrap writing is done on any type of paper, anywhere, to quickly document what one is seeing in space and time. Anecdotal records are mostly written in past tense and after the event. Most parents would have

Table I Developmental Profile Matrix Comparing Parent and Caregiver Observations

<i>Developmental Profile: Four to Eight Months, March 2014</i>				
	<i>Parent</i>		<i>Caregiver</i>	
	<i>As Expected</i>	<i>Not Yet Observed</i>	<i>As Expected</i>	<i>Not Yet Observed</i>

• Learning to cope with familiar and unfamiliar situations	+			–
III. Relationships With Other Children: Child to Child				
• Shows awareness of other children	+		+	

forgotten precisely what they observed, especially when they do not have the camera ready.

There is a need for professionals to learn about cultural competency and cultural competency practices. Some parents come from closed cultures where sharing personal problems is a taboo. In such cultures, parents are not forthcoming with their children's needs or family needs, and that hinders intervention. When professionals know how to relate to other cultures they will help the parents to be more open. The process of learning about variations in cultures is continual. It includes gaining greater appreciation of the intricacies of other cultures and more clarity about differences with one's own culture. As early childhood professionals gain more knowledge and awareness of other cultures, they may become better able to separate their biases and opinions from facts and find that it affects how they interact with parents and families.

OUTDOOR PLAY SPACES

Outdoor play spaces are influential components of the environments where young children live and learn. Irrespective of location, these settings possess a wide range of characteristics that may positively or negatively impact children's development. Government agencies typically monitor the health, safety, and accessibility of children's play areas found in public parks, restaurants, child care programs, and schools. Professional organizations and other agencies have sought to define the quality of children's outdoor play environments through various means, such as publishing position statements, developing standards, offering accreditation, and creating evaluation instruments. The relationship between outdoor play and children's health is substantiated by numerous research findings. For instance, outdoor play is considered a key factor in promoting cardiovascular fitness, building strong bones and muscles, curbing the effects of stress, and preventing childhood obesity. In addition, experts highlight many social, emotional, and cognitive benefits that may accompany frequent access to safe, challenging, and intriguing outdoor play spaces. This entry includes a brief overview of issues related to outdoor play in educational settings and provides discussion of appropriate, integrated physical, intellectual, and

relational spaces that adults can create to support children's development and learning.

Overview

No image better captures the popular essence of childhood than that of a young child engaged in outdoor play. Across cultures, adults seem to understand that when children play outdoors they are doing something important for their growing bodies, minds, and relationships. Physical play is essential to healthy child development. Running, jumping, catching, and climbing are examples of natural movements that support the growth and health of all the body's major systems. Opportunities for these types of movement are expanded when children play outdoors. Outdoor environments provide multitudes of unique sensorimotor experiences and challenges that promote cognitive development, that is, the very construction of knowledge. Also, as children interact with others during outdoor play, they meet social scenarios that compel them to discover new ways of relating to and respecting others—balancing their needs and ambitions with those of adults and other children.

A child's ability to safely and joyfully play outdoors is in many ways a measure of the well-being of the community to which the child belongs. Throughout history, adults have used their own play experiences and practical knowledge to construct outdoor play spaces for children. Beginning in the late 1800s, the emergence of specific places being set aside for children to play paralleled the growth of concern for public welfare in the United States. These pieces of property, allocated and designed to include recreational features for children, became known as *playgrounds*. In the last 150 years, changing philosophies and institutional priorities have caused dramatic shifts in how outdoor play spaces are conceptualized.

Context

Early childhood education professionals recognize that the amount of time designated for outdoor play and the characteristics of outdoor play areas reflect an important dimension of the quality of

an early childhood program. Unfortunately, play opportunities for preschool and primary-grade children during the school day have dramatically declined. Nationwide, many schools have reduced or eliminated outdoor play, even free recess, in the pursuit of higher academic achievement. However, information about how teachers can use children's experiences outdoors as a context for integrated learning is becoming more widely accepted.

Given the rich affordances accompanying outdoor play and the current status of play in many educational settings, educators can demonstrate their professional knowledge base by investigating sources of inspiration and practical information about how to create safe, stimulating, and effective outdoor spaces for children. Caring communities within neighborhoods, child care programs, and schools can realize the outdoor play environments that they imagine through careful organization, collaborative planning, and the creative acquisition of resources. Whether the goal is new construction or the transformation of an existing play space, it is necessary to maintain an awareness that children's play is a dynamic, open venture consisting of and enhanced by (a) physical spaces, (b) intellectual spaces, and (c) relational spaces.

Physical Space

Safety and health are the first and foremost priorities when planning any space for children's activity. Regardless of how elaborate and enticing the space may be, if it is not safe, it is unworthy of children. This entry cannot deliver a thorough description of playground safety. Therefore, due diligence demands the careful consultation of the numerous safety guidelines and recommended practices available. Adherence to all local regulatory and licensing codes regarding, for example, fall zones, protective surfacing, equipment spacing, fencing, and accessibility is required and must be maintained. Early educators should be aware that the school playground their students are expected to use might have been designed for older children. Developmental appropriateness is not confined to the classroom. Therefore, equipment should be the appropriate

size and provide a proper balance of risk and challenge for the ages of the children using the space.

Strategies for creating a welcoming space where each child finds ownership and a sense of belonging are equally valuable within outdoor environments. Clean and well-maintained materials, organized in designated storage that is accessible for all children's use provides an invitation for children to use materials responsibly. Displays of a large map and smaller signs designating areas of the playground help children understand how the spaces "work" together for general and the specific purposes. Clearly defined pathways provide safe passage for the curious and encourage exploration. Displays documenting children's activity outdoors and the preservation of children's creations allow children to connect and reconnect with meaningful learning and social experiences.

A high-quality physical space simultaneously offers diversity, novelty, predictability, flexibility, and lots of activity. Such an environment advances vigorous gross motor activity in endless ways. For example, within a single play session a child may run fearlessly during a game of tag; jump over boulders, logs, and other natural obstacles on an imagined adventure; pedal a trike along a path; and choreograph and perform a dance upon a pretend stage. An array of loose parts, balls, and other age-appropriate toys expand the options for purposeful self-directed play alone and with peers. Research indicates that play spaces including both manufactured equipment and natural, open-ended materials yield the highest levels of physical activity for children. Fixed playground equipment such as swings, climbing structures, and slides are dependable features that generations of children have enjoyed. Changeable features, such as sand or mud play areas; construction zones; gardening spots; and raised wood decking for performances, group experiences, and dramatic play afford children a plethora of experiences benefiting the physical domain and beyond.

Intellectual Space

Outdoor play engages children's minds as well as their bodies. Developmental theory and research

suggest that when children are exposed to diverse sensorimotor experiences and encounter problems, they construct new knowledge and form new strategies for thinking. High-quality outdoor physical spaces as described above are intended to serve as dynamic spaces that fuel the growing intellect. Rarely in schools do teachers plan for children's natural learning outdoors. Recess is better than no time outdoors, but simple strategies and readily available materials can transform times used to merely blow off steam into contexts with potentially higher educational value than the classroom alone.

While outdoors, children are able to engage in sophisticated intellectual activities with interest and enthusiasm. Making observations, forming questions and hypotheses, identifying problems, testing solutions, stating predictions, and countless other abilities can be documented when adults honor and encourage children's capacity for scientific thinking. Drawing children's attention toward wildlife and other natural elements activates their innate sense of wonder. Providing loose parts and open-ended materials for constructions of every sort creates conditions that require critical thinking, problem solving, and perseverance—and constant opportunities for children to learn how to work with others.

Relational Space

The phenomenon of young children playing together outdoors can be accurately described as a literal relationship laboratory. It is difficult to envision any situation where children's struggle to relate and interact is more visible and complex. If one imagines an impromptu gathering of neighborhood children, devoid of adult presence or agenda, it is likely that the image will include a display of very distinct personal communication styles. Eventually, alliances form, and roles are assumed. Power is displayed and conflict ensues. One can imagine how various problem-solving strategies could be suggested. In short, children have amazing capacities for managing their social worlds. Surprisingly, research indicates that these sorts of scenarios where groups of children gather

outside of the range of adult supervision and capably work out social problems have become quite rare. Furthermore, as a result, today's children may be less competent in managing social relationships than children have been in the past. In many programs and schools, teachers work continuously to maintain behavioral expectations conducive to the production of academic work. When things go awry among children, often the teacher determines the source of the problem and pronounces the solution. This practice denies children the opportunity to experience authentic relationships and learn how to successfully navigate them. Fortunately, a large body of literature exists that provides principles and strategies for building community and expanding children's social competencies within the classroom.

Periods of time outdoors are prime occasions to create a positive relational space. Cooperative peer relationships originate within children's warm, secure relationships with adults. Teachers activate the relational space outdoors by being physically and emotionally present. A high-quality outdoor play space cannot exist without sufficient adult supervision. Safety standards require that each child be visible to at least one adult while outdoors. To actualize the outdoors as a relational space, adults go beyond watching out for trouble and assume the role of observer, model, and coach. A relational space coexists with the intellectual space and the physical space. When groups of children enjoy the features, elements, and atmosphere that characterize a rich physical environment, they continuously encounter events that challenge their social skills. Waiting for a turn to use a swing, being accidentally hit by a runaway trike, asking for a friend's help to balance a board while building the roof for a hideout, and thousands of other possibilities are occasions for authentic learning about managing emotions, expressing feelings in responsible ways, and suggesting solutions to remedy conflicts. The relationships formed with adults and early friendships provide the secure foundation, practical examples, and resources to draw from when learning to relate to others seems difficult. The

intellectual space—where new encounters are met with enthusiasm, where it's okay to be uncertain or wrong, and where persistence is rewarded—strengthens the relational space and creates a positive social climate with long-term implications. Conceptualizing and creating outdoor environments that integrate physical, intellectual, and relational dimensions offer young children the opportunity to develop traits and skills that can translate into more civil societies.

P

PARAPROFESSIONALS

Paraprofessionals are individuals who provide assistance to professionals by conducting various support activities. In the education profession, the term *paraprofessional* is typically used to identify those who provide support for teachers by working with individual children in a classroom, monitoring noninstructional activities during the school day, and/or providing clerical support. Paraprofessionals who work with young children may also be referred to as teacher assistants, teacher aides, support staff, or paraeducators. Education and experience requirements for paraprofessional positions vary based on position funding requirements and qualifications as determined by the hiring agency.

The Role of an Early Childhood Paraprofessional

Early childhood paraprofessionals work with children ages birth to age 8. They may provide general support to a program, support for a specific group or classroom of children, or support to individual children. Paraprofessionals in any of these roles may also provide clerical support, supervise or monitor children or a specific child during noninstructional activities, or provide instructional support to children or a specific

child. Hiring agencies determine a paraprofessional's qualifications, duties, and responsibilities. If the position is funded by the federal government as a Title I paraprofessional, the person who is hired to fill the position must be designated as highly qualified by meeting specific stated requirements.

Early childhood paraprofessionals may work in public or private schools, in early childhood programs, or for agencies or organizations that provide support for families and children. Schools educating preschoolers, kindergarteners, and first, second, and third graders may hire paraprofessionals to fill positions for specific populations of students financed by federal or state grants or by local funds. For instance, a school district may hire a paraprofessional to provide support for a child who has a sight or hearing impairment. Early childhood programs, such as programs that offer full- or part-day education and care for children outside the home, may also finance paraprofessional positions through federal, state, or local funds to work with a child with an identified special need, such as a child with a mobility disability. Early childhood programs may also use parent tuition funds to provide a paraprofessional for daily classroom support and to meet staff to child ratios required by state regulations. Agencies or organizations that serve families and children may also hire paraprofessionals to serve in the roles, such as home visitor or parent mentor.

Clerical Support

Paraprofessionals may be assigned clerical support responsibilities and duties. Support duties may include such tasks as completing routine attendance and report paperwork. By conducting these routine duties, the paraprofessional provides support that allows the teacher to spend more time on advanced instructional duties.

Monitoring and Supervising of Noninstructional Activities

Monitoring children during meals or snacks, restroom breaks, playground activities, arrival or departure times, and/or preparation or cleanup of classroom activities contribute to the school, program, and classroom community. Paraprofessionals serve as positive role models and often build a special bond with children during these transitional and routine times. Supportive interactions with children during these noninstructional periods help children develop skills in the social and emotional domains.

Instructional Support

Primary among the duties and responsibilities of paraprofessionals is the task of providing instructional support for groups of children or individual children. A teacher may develop an instructional plan (lesson plan) and a paraprofessional may implement the plan under the supervision of the teacher. For instance, the classroom teacher may lead a literacy activity with a small group of children and the paraprofessional may lead another small group of children in a different activity that was planned by the teacher. Paraprofessionals, following directions from the teacher, interact with children involved in learning center activities and focus on specific vocabulary development and communication skills.

Instructional support may also be provided to individual children with special needs. Often the type of paraprofessional instructional support is determined by a child's Individual Education Plan that is developed by a team of professionals and family members. For example, a paraprofessional

may be assigned to work with a child who has a physical or emotional disability, a child with limited English proficiency, a child who lacks self-regulation skills, a child who will benefit from one-on-one instructional time, or a child with a diagnosed learning disability.

Qualifications of an Early Childhood Paraprofessional

Paraprofessionals may possess a variety of educational and experiential qualifications. When providing instructional support, paraprofessionals must have knowledge of learning standards and associated skills, as well as a deep understanding of child development, best practices, and developmentally appropriate practices. Title I, Part A of the Elementary and Secondary Education Act has funding provisions for paraprofessionals who provide instructional support for children designated as disadvantaged. Title I paraprofessionals must meet the federal definition of "highly qualified" by meeting specific competency requirements. In this context, to be highly qualified, a paraprofessional must have a minimum of an associate's degree or 2 years of college credits and passing scores on a qualifying exam or some other acceptable assessment measure. For paraprofessional positions not financed with Title I funds, each state and local agency or school may set paraprofessional position qualifications and job descriptions.

Some community colleges provide paraprofessional certificates or associate's degrees. Numerous training resources are available that focus on paraprofessional skills, knowledge, and dispositions required to provide effective support and help children meet learning outcomes, state standards, and Common Core standards. In addition, resources are available to assist those supervising paraprofessionals to create effective, productive team approaches that will positively affect student/child learning. The National Resource Center for Paraeducators is a nonprofit, professional organization that provides resources and support for paraprofessionals and supervisors.

PARENT AND FAMILY INFLUENCES ON ACTIVE FREE PLAY

Active free play is a specific type of play, defined as spontaneous and voluntary activities that take place outdoors with minimal direct adult supervision or control. It may be social or solitary, can involve games with informal rules, and must include bursts of physical activity. Children engage in active free play in parks, playgrounds, streets, and natural environments. Examples of active free play include running, climbing, chasing, and informal games, but not organized sports. Active free play research often also includes the study of active transportation, specifically in terms of children walking or cycling to play areas.

Value of Active Free Play

Active free play is important for healthy cognitive and social development. It provides children with opportunities to learn how to work in groups, share, negotiate, resolve conflicts, and learn self-advocacy skills. Exposure to natural outdoor environments is associated with reduced prevalence of cardiovascular,

respiratory, neurological, and digestive diseases, as well as reduced depression and anxiety.

Decline of Active Free Play

Children's active free play has declined significantly over the past 50 years as there has been a shift toward indoor sedentary lifestyles. Such indoor sedentary lifestyles contribute to chronic conditions among children including obesity, asthma, attention-deficit/hyperactivity disorder, and vitamin D deficiency, all of which have increased in North America. Parents and other caregivers are the most frequently reported barriers to children's engagement in active free play due to their safety concerns.

Parent and Family Influences

The concept of the good parenting ideal can be used to examine how and why the restrictions parents place on their children have changed. The good parenting ideal essentially refers to how parents understand societal expectations for their parenting. It is what parents perceive to be considered good parenting by other parents in their community and society, and is therefore subject to evolving social and cultural norms. For instance, some parents feel the need to monitor their children at all times in order to be seen as good parents, whereas allowing children to play outdoors unsupervised would be a feature of poor parenting. Furthermore, traditional autocratic parenting styles have fallen out of favor in recent times and been replaced with child-centered, authoritarian, and, in some cases, indulgent and overprotective approaches. In the 1950s and 1960s, the family home was a place for adults and strict control, while outdoors was a place for children. In more recent times, outdoor spaces became adults' areas while private spaces, such as the family home, became children's areas.

Understanding Active Free Play From an Ecological Perspective

Social psychologists have observed that there must be synergy in the life space between individuals

and their social environments to produce positive outcomes. Ecological theories build on this concept and are typically based on the notion there are different levels of “social ecology” (i.e., social environments). The ways in which individuals interact with these social ecologies influence their behavior. Ecological approaches can be used to understand parents’ influence on active free play. Following the work of Bronfenbrenner, scholars can view behavior as a function of interactions between individuals and features of their social ecologies. Individuals interact with several levels of ecological systems, from more proximal microsystems to more distal macrosystems (ranging from family, school, neighborhood, and community to surrounding political and economic systems, and culture). The use of an ecological approach facilitates the analysis of more individual factors (e.g., child characteristics), proximal issues (e.g., parenting), how they are influenced by more distal issues (e.g., neighborhood and social factors), and relationships or intersections between different systems.

Ecological Determinants of Active Free Play

Child characteristics have been associated with engagement in active free play. With increasing age children are usually more likely to be permitted by their parents to engage in active free play. Children are allowed more opportunities to play if their parents perceive they are competent enough to recognize and appropriately respond to potential dangers in the outdoor environment (i.e., they are “streetwise”). Boys are usually permitted more freedom than girls, specifically in terms of being allowed to play outdoors more frequently, under less supervision, stay out later, and have a larger spatial range away from the family home.

As noted earlier, parents’ and other caregivers’ safety concerns are the major barrier to active free play. Parents are concerned about safety with respect to strangers, bullies, teenagers, and traffic. Safety concerns are reported in both urban and rural settings. Parents attempt to manage their

safety concerns through some forms of surveillance, which can include setting spatial and time limits for their children (i.e., children can go only to certain locations and have to be home by a certain time), driving them to locations, allowing them to play only with friends, or insisting they carry cell phones.

Features of the neighborhood and physical environment influence active free play. There are fewer children in neighborhoods, meaning there is an absence of friends to play with and decreased “safety in numbers.” On the other hand, the accessibility and proximity of play areas from the family home has a positive influence on the likelihood of children engaging in active free play. Children are more likely to use, or be allowed by their parents to use, playgrounds that are well maintained.

A reduced sense of community is one of the reasons why parents are reluctant to allow their children to spend time outdoors. This involves not knowing neighbors or other families in the local community. Broader societal and economic forces have meant that children’s play spaces and playtime have become increasingly privatized. Researchers have suggested that, to revive active free play, there must be an increased sense of community that involves people knowing their neighbors, spending more time outdoors in their neighborhoods, and organizing community-oriented events.

Social Traps

Parents face *social traps* that restrict children’s engagement in active free play. For example, if parents restrict their children’s freedom to spend time outdoors, there are fewer children to play with outdoors, thus further restricting parents’ willingness to let their children go out and play due to the absence of safety in numbers. If parents are more likely to drive their children than let them walk due to concerns about road traffic, they therefore contribute to increasing the amount of road traffic. Combined, these social traps reduce the number of people who spend time outdoors in a neighborhood, diminish a sense of community and social cohesion, and increase perceived safety

concerns. These examples highlight the reciprocal nature of factors at multiple levels of social ecology that influence children's active free play.

Interventions

Traffic calming, crime prevention, and community policing strategies offer one set of alternatives for addressing parents' safety concerns. However, there is an urgent need for more intervention research to revive active free play. Existing evidence suggests community-level interventions targeted at building social cohesion are required. Avenues to engage children in planning decisions are required for creating community-oriented change that caters to children's needs. Researchers and planners should "see" with the eyes of children and create play opportunities that serve children's needs rather than adults' needs.

PARENTING EFFECTS ON CHILD DEVELOPMENT

Parenting is a multidimensional construct that embodies many behaviors that parents engage in for and with their children, including nurturance, education, discipline, monitoring, management, and providing materials. It also includes attitudes and beliefs that impact parents' behaviors such as expectations and progressive versus traditional child-rearing beliefs. Parenting is developmental and dynamic in that knowledge and behaviors of parents change over time due to various factors including age of parent and child, number of children, child skills and temperament, and multiple contexts and circumstances.

Overview

Key aspects of parenting found to impact children's development are sensitivity/nurturance, cognitive stimulation, resources (including time), and management. Highly sensitive parenting includes expression of affection and warmth, as well as emotional availability (e.g., praising or cuddling). Cognitive stimulating parenting includes intentional teaching to enhance children's skills (e.g., assisting children in learning their letters or solving a puzzle). Resources are referred to materials, opportunities, and time that parents provide to children that support their development (e.g., visit to the zoo, books, contingent conversations). Management encompasses parents' engagement and attention to the needs of their child ranging from management of children's health needs and daily routines of the household (e.g., bath time) to the amount of television time.

Other aspects of parenting noted in the literature include parental expectations and beliefs, closeness and conflict between parents and children, and stress due to parenting. While these aforementioned parenting behaviors and attitudes are thought to be universal, caution is needed when examined through the lens of diverse families and communities, whose behaviors and attitudes are influenced by the sociopolitical history of the U.S. (i.e., racism and discrimination), culture, and economic status.

Theory

The bioecological theory and two key economic frameworks provide support linking parenting and children's development. The bioecological theory states that various systems impact children's development, but one system in particular, the microsystem, is more proximal to children's development and it includes parents and families. Two frameworks have been presented showing how families' economic status is linked to children's development through parenting. The first, the family investment model (FIM), suggests that socioeconomic status—income and education—provide one with the economic stability and ability

to purchase goods and materials, as well as provide opportunities and experiences that promote children's development. The second, the family economic stress model (FESM), suggests that the psychological stress associated with economic deprivation and hardship disrupts parents' ability to be responsive and engaged with their children, subsequently impacting children's functioning and development. These two frameworks indicate that with all factors being equal, when parents are economically and emotionally invested in their children, children are likely to show better cognitive and social competence.

While studies have empirically supported these theories, some studies have questioned their saliency for diverse families, who are living in different contexts in comparison with the majority White U.S. family. When parenting is viewed in context, questions arise about what constitutes investment, emotional distress, and economic deprivation.

Research

Vast evidence exists showing the association between various parenting behaviors and attitudes and children's cognitive and social development. Numerous studies have documented that the quality of the home environment, including cognitive stimulation and sensitive interactions between parents and children and available resources in the home (e.g., books), are associated with children's cognitive and socioemotional outcomes regardless of income and ethnicity. A meta-analysis examining various constructs of parenting has shown that parental expectations are strong predictors of children's later outcomes. Similarly, parents with child-centered beliefs are likely to have children with higher cognitive skills compared with parents with traditional or adult-centered beliefs. Other aspects of parents, namely depressive symptomatology and stress function, have been linked to children's development.

However, while many of these parenting indicators have been found to be generally universal, some studies note that some parenting behaviors and attitudes have differential effects on children's

development. For example, parenting behaviors viewed from a Eurocentric lens as controlling and intrusive, shown to have negative impact on White children's development, have been found to be less harmful for children of color, particularly African American children, especially within the context of warmth. This is the similar case for parenting behaviors viewed as permissive, as is the case with Hispanic families. Thus, more culturally relevant tools and approaches are needed that better capture the extent of parenting activities beyond those based on middle-class European American families.

Intervention

Many studies and reports, including a recent one funded by the U.S. Department of Health and Human Services, provide a wealth of evidence about the importance of parenting and family engagement for optimal child outcomes. Recently, more attention has shifted to examining effective ways to support and strengthen parenting. Approaches and strategies found to strengthen parenting included the following:

- Focus on family centeredness that honors and respects families' values and choices and provides supports to strengthen family inclusion in order to meet the needs of their child's development. Family-centered practices include compassion and active listening, support and belief of parenting capabilities, and responsiveness to parenting needs. Being family centered also means integrating the culture and community through, for example, celebrating the cultures of all families and interacting with families and/or teaching children outside of the school context and within their communities.
- Practitioners serving as the change agent and role model to support home-based engagement and support. Parental home-based engagement is found to be particularly more effective for children's outcomes than school-based involvement. Thus, practitioners can serve as role models to support families to engage in enriching and developmentally appropriate activities and interactions to support children's learning.
- Frequent interactions between home and school (including early education programs). Strong home-school connections are based on trust, teachers' openness and knowledge of culture without bias, and communication and collaboration. However, this connectedness between families and schools can only be established through frequent reciprocal and mutual collaboration and communication.
- Opportunities to build families' social capital and network through peer interactions and community engagement. Families' social networks and capital have lifelong impacts, and directly and indirectly impact children through examples such as impact on parents' psychological well-being. Providing opportunities to peer networks and community supports can bolster parents' positive sense of self, improving positive parenting, and reduce parental material and mental hardship.
- Recruit, train, and support emerging parent leaders through mutual respect, equity, shared power, and recognition of strengths. There are limited studies on the impact of parental advocacy on family engagement and child outcomes. Research nevertheless finds that families involved in the organizational structures of programs are likely to be more engaged. Increasing parental advocacy engagement requires commitment and willingness to share power and recognize families' assets.
- Opportunities for active engagement in all aspects of school (e.g., organization, management, curriculum) and using families' funds of knowledge. Engaging families requires one to acknowledge that parenting is a developmental process based on one's culture, experiences, and traditions. Therefore, parents are always learning how best to support their child based on their ability, their child's need, and their context.
- Utilization of resilient/strengths-based approaches. Families' well-being, including mental health and economic viability, must be considered when determining ways to strengthen family engagement. Studies abound about the deleterious impact of poverty, and chronic poverty on parental

mental health and subsequently family engagement and child outcomes. Addressing families' self-sufficiency is reemerging as an avenue to ensuring that parents are emotionally stable and secure and can only be accomplished through approaches that respect families' values and choices and provide supports.

Core Components of Effective Parenting Programs and Practices

Evidence-based or promising programs are focused on either micro aspects of parenting (e.g., parent-child relationship) or macro aspects (e.g., advocacy and social capital). Components of effective parenting programs are

- clear focus on area of focus (e.g., parent-child relationship, parental advocacy),
- identification of critical elements of program,
- well-developed sessions and activities,
- ability to be systematically and rigorously evaluated,
- direct service and support to families and less focus on supporting staff competence, and
- integration of culture and community.

As parenting is viewed as one of the critical elements in ensuring children's optimal development, along with community and education institutions, culturally based and informed research and practice are needed, especially as the United States becomes more diverse. A deeper examination of aspects of parenting that is most critical for children's development is needed to ensure that programs are aligned with parenting dimensions found to be most effective. In addition to alignment of program goals, competence of practitioners working with families must be further developed to ensure that the necessary skills, knowledge, ability, and attitudes are aligned with programmatic goals that support optimal parenting.

PARENTING SUPPORT AND EDUCATION

As children build essential academic, social, and physical competencies in the early childhood years, their parents—their first, most constant, and most invested caregivers—play an essential role. Apart from their genetic contributions, parents serve as models from whom children learn a great deal of their vocabulary, as well as guides who support the development of self-regulation and prosocial skills, and gatekeepers who determine how, and with whom, they spend their time. The importance and complexity of parenting makes it an immensely challenging task, particularly when children are young and highly dependent on their families for care. Moreover, an increasing proportion of households must balance these intense family commitments with workplace demands and other community roles. Thus, it is likely that most parents of young children, at some point in their child's and family's development,

could benefit from additional education and support to help them refine their parenting and optimally support their child's growth. Such benefits may be particularly great among parents in low-income households and communities, who often face an usually high number of challenges with relatively few resources, and whose own knowledge and social capital, while potentially extensive, may not be well aligned with the expectations of the school system into which children are headed. This entry explores the diverse spectrum of parent support and education resources available to families of young children, especially those in poverty, highlights "active ingredients" that support effectiveness of these endeavors, and briefly describes key components of several widely disseminated, effective models.

Modern Landscape of Parent Education and Support Services

Parent support efforts have been a prominent thread in America's educational tapestry throughout the nation's history. In the late 19th and early 20th centuries, many endeavors were informal (e.g., casual meetings) and largely directed toward mothers in middle- or upper-income settings. However, the 1930s through the 1960s witnessed a shift toward more formal efforts to support families in need, including the advent of the Head Start program and the subsequent inception of Even Start and Early Head Start initiatives. One important facet of the evolution of parent education and support during this period involved the application of the term *parent* to all primary caregivers, including biological or adoptive mothers and fathers, grandparents or other extended family members, and/or other guardians; in fact, the past decade has seen increased emphasis on fathers and grandparents as well as mothers. Another key change was that parent education and support programs generally began to take an "assets-based" approach that recognizes and capitalizes on the strengths of families and communities while also providing new ideas and tools to expand parents' skills and well-being and, ultimately, to benefit young children.

Spectrum of Support and Education

At present, parenting support and education takes a wide range of forms that vary along several dimensions.

Target Outcomes

The target outcomes differ greatly across parent support models. Some parent education endeavors aim to improve parents' own economic or personal well-being (e.g., job readiness, mental health), while others target parents' caregiving skills (e.g., responsiveness to children, use of consistent and fair discipline with children), and still others focus on helping parents target specific child skills (e.g., helping children build language and literacy skills, or helping children manage challenging behaviors).

Intensity of Support

Support and education efforts are provided with varying levels of intensity, from relatively "light touch" efforts such as nudges or tip sheets sent home from daycare or preschool, to one or several workshops delivered to groups of parents, to repeated visits to and consultations in the family's own home (generally termed *home visits*) by a trained expert. In general, programs with more extensive goals, such as improving the quality of parent-child attachment, involve greater dosage (i.e., more sessions) over longer durations (i.e., several visits, perhaps even over several months), whereas programs with more specific goals, such as increasing the frequency of parent-child book reading, can be effectively delivered with fewer contacts over less time.

Providers of Support

The providers of these parent education and support programs vary as well. For example, early childhood education programs (e.g., Early Head Start, Head Start) are often highly effective providers of support and education services for families of participating children; however, they have little access to families whose children are not already enrolled. In contrast, a wider audience can be

reached by local and state agencies and community organizations, as well as pediatricians and other health providers. Yet more diversity emerges regarding differences in the individuals who are actually delivering information to families, particularly with regard to their caseload and training. Here again, programs targeting broad, complex parent and family goals that require significant time often mandate higher requirements for formal project-related training (e.g., a series of workshops resulting in certification), perhaps in addition to a degree in a particular field of expertise (e.g., nursing or education professionals). Conversely, programs with more constrained goals can sometimes be effectively delivered by full- or part-time para-professionals or even by volunteers.

Key Ingredients in Effective Support and Education Models

Meta-analyses suggest that effects of parent education and support on parents' perspectives and practices, as well as on children's outcomes, are mixed. However, given the variability of their nature and aims of these programs, it is difficult to draw meaningful conclusions across these projects. Instead, it is likely that a few key program features support success, and that they can be implemented in varied ways.

Evidence-Based Content

First, in order to help parents build knowledge and implement practices that result in stronger outcomes for both adults and children, it is essential that parent education programs target content that is evidence based and supported by rigorous analysis. For example, if the goal of the parent support program is to foster children's language and literacy skills through shared book reading, the program would need to provide parents with specific guidance, culled from the research, regarding how to engage children in book reading through discussion of new words, letters, and the sounds in words. If the information provided to families is not of high quality, families will not

derive much benefit. Conversely, high-quality information may set off a virtuous cycle, as families see positive effects of new ideas or practices in their own lives and then become more motivated to keep using strategies and to learn more.

Effective Training

Second, it is essential that this high-quality information be provided via clear and concise methods that families can understand. Moreover, particularly in more intensive, longer programs, families are more likely to entertain and ultimately try out new methods if they have built a personal relationship with the representative of the program. Ultimately, attrition is lower and uptake is higher when parents feel that their unique family circumstances are heard and appreciated, and that their point of contact with the project is knowledgeable and truly invested in them. Fostering such good relationships depends in large part on selecting representatives for a program who understand the broader community culture and are open to learning about families' own cultures; some programs aim to recruit personnel from that community to support this goal. Effective programs also need high-fidelity techniques for training personnel.

Feasibility for Families

Finally, even when high-quality information is effectively provided by well-trained and supportive parent educators, recommended ideas and strategies must be feasible for families to use in the course of their everyday lives. Extremely complex or time-consuming practices may be very challenging for families to use, particularly in households facing many stressors. Poor feasibility may discourage families from remaining involved in the program and result in disengagement and dropout.

Widely Used Programs With Evidence of Effectiveness

Many American families potentially have access to one or more parent education and support resources. Funding most often comes from federal

programs (e.g., Maternal, Infant, and Early Childhood Home Visiting [MIECHV] Program) or state funding that specifically targets families in poverty. Several of the more prominent and better researched models, each with evidence that it effectively changes its targeted outcomes, are briefly detailed below.

One of the more widely available programs, serving approximately 4.4 million families in poverty annually, is Reach Out and Read (see www.reachoutandread.org), targeting early language and literacy by helping pediatricians provide books and guidance on shared reading to parents of young children at well-child checkups. Also relatively widely available are Head Start and Early Head Start programs, providing center- or home-based care for more than 1.1 million children in poverty per year. These programs primarily support early cognitive, social, and physical development, but they also offer many family support services as well. Services include some home visits (generally two per year in center-based settings, and weekly visits in home-based settings), as well as workshops on parenting, job training, or other programming determined by each Head Start program. They also have full-time family liaisons on staff to help parents with a variety of issues.

More intensive, individualized programs with broader goals (e.g., supporting children's general school readiness by supporting parents' teaching, warmth, and management of children) often include extensive home visiting and reach fewer total families. For example, Parents as Teachers (PAT) serves approximately 200,000 families around the globe, fostering children's cognitive and social school readiness by enhancing a variety of parenting skills. This model provides home visits (from weekly to monthly frequency) by individuals from the community with at least 3 days of program-specific training over the first several years of a child's life, as well as group meetings that allow parents to learn together. In a similar vein, Home Instruction for Parents and Preschool Youngsters (HIPPY) serves approximately 16,000 American children per year. Like PAT, HIPPY involves home visitors from the community who

receive several days of program-specific training. They offer families of children ages 3 to 5 biweekly home visits and biweekly group meetings in which families role-play new techniques for building children's cognitive and social school readiness.

Perhaps most intensive are programs such as Healthy Families America, which seeks to reduce child maltreatment and enhance healthy development in very underresourced families through a variety of parent- and child-focused pathways. Beginning in infancy, children are visited by a support person with at least 4 days of program-specific training as often as weekly over 3 to 5 years. As another example, the Nurse-Family Partnership, which broadly targets mother-child well-being from pregnancy through 2 years of age, involves degreed nurses with additional, specialized program training who provide home visits approximately bimonthly through the child's second birthday.

Parent education and support programs take a variety of forms and, when well designed, provide essential, effective aid for families of young children.

PARENTS AS TEACHERS

The term *early childhood education* typically encompasses education for children from birth to age 5 (kindergarten entry) or, often, age 8 (third grade). Early childhood education services include center-based care for infants and toddlers, early Head Start, prekindergarten, and kindergarten. Common to all of these services is that they target the child, but not typically parents. Parenting education is of central importance to effective early childhood education.

It is a well-established fact that brain development begins before birth, and a tremendous amount of critical, deterministic development takes place in the first few years of life. The vast majority of a child's earliest experiences take place during interactions between children and their parents within the home environment. Very early experiences, starting prenatally and through the first year, have a strong impact on child development. Parents are the key drivers behind those experiences. It is critical, therefore, that effective early childhood education encompass parenting education. Children do not come with an "owner's manual," but parenting education can help parents develop their own, tailored to their individual child's development. A widely implemented delivery mechanism for parenting education is home visiting.

This entry describes the evidence-based Parents as Teachers model as an example of how home visiting serves as an important component of early childhood education.

Fundamental to the majority of home visiting models is the theory of change undergirding the

models, emphasizing that impacting parenting knowledge, attitudes, behaviors, and family well-being results in impacts on the child's developmental trajectory. Also common to most home visiting models and supported by learning theory and research is that services are taken to the family, take place in the family's home environment, and tend to be delivered over an extended period of time, often 2 years or more.

Parents as Teachers (PAT) is the nation's largest home visiting model. Developed and first implemented in Missouri in 1981, PAT has been educating and supporting parents in providing early learning experiences and environments that result in children who are physically, emotionally, and socially set on a trajectory for school success. Trained and certified parent educators deliver personal visits, typically in the home; offer group connection activities; conduct developmental, health, hearing, and other screenings; and make referrals to community, health, social service, and other resources as needed to expectant families and families with children birth through the kindergarten year.

The PAT approach is grounded in two related theories: Urie Bronfenbrenner's Bioecological Theory and Family Systems Theory, informed by the work of Dr. Murray Bowen. According to Bronfenbrenner, development is largely the result of relationships children have with their parents and other caregivers, and these relationships are influenced by the broader environment including extended families, neighborhoods, and larger society. A relationship with a parent educator is an example of a broader influence. Family Systems Theory grew out of Systems Theory, which holds that any system can be viewed as an organized whole. In Family Systems Theory, families are systems, and family members make up parts of the system. Each part of a system has characteristics: There are relationships between and among family members and each relationship impacts other relationships. Each family member, parents and children as well as others who may live in the home, affects and is affected by the behaviors of other individuals within that system. Families are in a

constant state of change requiring members to engage in constant efforts to restore balance.

Examples of how PAT embraces the main concepts in these two theories include the following:

- Services are provided within the family context, rather than outside of it.
- PAT is interaction- and relationship-focused—the focus is on both parents and children in interaction with one another—rather than solely child focused or parent focused.
- The PAT parent educator has a role within the family's larger social context as part of the family's social support network.
- PAT services are delivered by professionals housed within organizations or agencies in the families' community providing connections to the broader community, rather than by independent operators.
- PAT services are adapted to the broader social, cultural, and societal contexts in which families exist and incorporate resources beyond the immediate family members.

The goals of Parents as Teachers are fourfold:

- Increase parent knowledge of early childhood development and improve parenting practices
- Provide early detection of developmental delays and health issues
- Prevent child abuse and neglect
- Increase children's school readiness and school success

The personal visit is the heart of the PAT model. Guided and informed by a research-based and evidence-informed curriculum, parent educators emphasize development-centered parenting, parent-child interaction, and family well-being on every visit; share parenting strategies and child development information; engage parents in goal-setting activities; identify child, parent, and family needs; and connect the families with needed resources.

Research confirms that parents and children who receive Parents as Teachers services benefit in the following ways:

- PAT parents engage in more language and are more likely to promote reading in the home.
- PAT parents show significant improvements in parent knowledge, parenting behavior, and parenting attitudes.
- PAT participation was related to 50% fewer cases of suspected abuse and/or neglect.
- Children enter kindergarten ready to learn, and PAT participation helps narrow the opportunity gap for low-income children.
- PAT children continue to achieve school success into the elementary grades.

Home visiting models such as Parents as Teachers deliberately put parents at the helm of their child's early education, where they belong. As such, parenting education, especially through home visiting, has been shown to be a successful support to effective early childhood education.

PARENTS WHO ARE LESBIAN, GAY, BISEXUAL, TRANSGENDER, OR QUEER

Over the course of the last several decades, there has been an increase in the visibility of people who

are lesbian, gay, bisexual, transgender, or queer. Individuals who identify as *lesbian* are women who are attracted to other women and likewise the term *gay* is often used to refer to men who are attracted to other men, although the term *gay* can also be used for women. *Bisexual* is a broad term that usually means a person who is attracted to both men and women. The terms *lesbian*, *gay*, and *bisexual* are related to sexual orientation. *Transgender* is an umbrella term used for people whose anatomy doesn't match their gender. For example, a child can be born with male anatomy but as the child grows up, this individual is a female. A person who is transgender may choose to undergo hormone therapy and/or reconstructive surgery to transition into his or her inner gender. For many people, the term *queer* may have negative connotations, but it is a term used in the lesbian, gay, bisexual, transgender, and queer (LGBTQ) community in the same way other negative terms have been reclaimed by underrepresented groups. *Queer* is also term that has gained currency in the academy since the 1980s, with the development of queer theory and establishment of queer studies programs.

The terms *lesbian*, *gay*, *bisexual*, *transgender*, and *queer* are only a few of the words that can be used to denote someone who is other than straight and/or "male" or "female." For a more complete discussion on other terms used for sexual orientation and gender identity/expression, readers can refer to *The Social Justice Advocate's Handbook: A Guide to Gender* written by Sam Killerman and published in 2013.

A conservative estimate of the number of U.S. children with parents who are LGBTQ is 6 million. We do not have census data to determine if there are more parents who are LGBTQ now than previously as the U.S. Census only began asking questions about the sex of a partner beginning in 2000. An assumption could be made that there has been an increase because there are now more parents who openly identify (come out) as LGBTQ because there are more openly gay characters in the media, or because legal changes directly related to people who are LGBTQ, including the right to marry and

adopt children, have opened up new opportunities for people who are LGBTQ to start families. However, it should be noted that there have always been parents who are LGBTQ, and it is more likely that we are not seeing an increase in numbers, but instead we are witnessing the social change that results in more people feeling safe enough to come out.

Whether the number of parents who are LGBTQ has increased is not essential for those working in the early childhood field except to understand that the likelihood of having families whose children are in early childhood settings with LGBTQ parents is high, even in rural areas within the country. What is essential for early childhood educators is to have an understanding of the lived experiences of these parents and their children and to support all families.

Marriage and LGBTQ Parents

Just as marriage is not a prerequisite for a straight couple or single person to become a family, the same is true for parents who are LGBTQ. There are parents who are LGBTQ who choose to cohabitate and parents who are LGBTQ and single, just as there are straight parents who choose to remain unmarried or who are single. The difference is that until 2015, straight adults across the United States had the right to get married but the same right was not extended to LGBTQ couples in all U.S. states.

Becoming a Family

Families headed by LGBTQ parent(s) are made in a variety of ways (just as heterosexual parents make their families in a variety of ways). Some of the children in families with LGBTQ parent(s) are from previous heterosexual relationships in which the children are the birth children or adopted children of a once married or partnered straight couple. Other families are made after a same sex couple form a union, or a single LGBTQ person may be parenting alone either by choice or because a relationship has dissolved. Single or coupled/married males may adopt or use a surrogate.

The surrogate could be a friend or family member or could be someone who has entered the couple's life for the sole purpose of carrying and giving birth to the child. Although the surrogate gave birth to the child, in most cases one or both of the fathers will then adopt the child. Single or coupled/married lesbians may choose to adopt or give birth to a child. When choosing to give birth to a child, there are a variety of ways in which this can happen. A sperm donor may be employed, and that donor could be either someone who is known or an anonymous donor from a sperm bank.

For parents who are transgender, becoming a family can be as complex as it is for parents who are lesbian, gay, or bisexual, but there are additional complexities. If a parent is transitioning (anatomically) after children are a part of the family it may be impossible for the parent to be listed on the birth certificate because the certificate would need to be changed. For example, if a child was born to a "mother" and "father" as is listed on the birth certificate but then one parent transitions so that there are now two fathers, depending on the state in which the family resides, there may not be an option for two fathers to be listed on the birth certificate and thus have legal parental rights to the child. Single or partnered/married people who are transgender and trying to carry or adopt a child may find adoption agencies, sperm banks, or surrogacy agencies discriminate against them. People who are transgender are more likely to be discriminated against than people who are lesbian or gay with regard to having children.

Rights of Parents

As noted previously, there are LGBTQ parents who are single parents but in many cases they are the legal parent of their child(ren). For those families with two parents of the same sex who have children together, there are issues that are essential for early childhood educators to be aware of that may lead to additional stress for the families. On June 26, 2015, the U.S. Supreme Court ruled that the U.S. Constitution guarantees the right for same-sex couples to marry in all 50

U.S. states. Associate Justice Anthony Kennedy stated in the majority opinion: “The Court, in this decision, holds same-sex couples may exercise the fundamental right to marry in all States.” However, since this is a very recent ruling, in states that did not legally allow same sex marriage prior to the Supreme Court decision, it was often the case that only one of the parents was noted as a legal parent (listed on the birth certificate). It is possible that a number of couples who have since married have not taken steps to change the legal status of children. Additionally, if the family has been formed through adoption, there are states that permit only one of the parents to adopt the child. Again, this is the legal definition and not the working definition of *parent*. This is important information because if a person who is parenting is not listed on the birth certificate, that person’s rights as a parent are not protected. There have been cases in which there are two parents (moms) and the parent who is listed on the birth certificate has died, yet the other parent does not have a legal right to raise the child. In many cases, the family of the deceased parent has legal rights to the child and asserts that right with the removal of the child from the surviving parent.

The Role of the Early Childhood Educator

Early childhood educators are oftentimes the first connection parents have to a school or school setting such as a child care center, in-home family day care, or Head Start program. These initial interactions are important for all families, but for parents who are LGBTQ, their child(ren)’s first teachers can make the difference between the family feeling welcomed and supported or feeling invisible, unwelcomed, or even discriminated against. These initial, negative feelings toward the school setting can set the stage for subsequent years. Many times, the interactions that cause feelings of being unwelcomed by teachers are not necessarily intentional or even realized by the teacher but instead an act or omission that happened unknowingly.

Welcoming LGBTQ Parents Into Early Childhood Settings

Perhaps the most important thing a teacher or administrator can do to welcome LGBTQ parents into their settings is to educate themselves on the particular laws in their given state regarding people who are LGBTQ and to then consider how those laws impact families. By understanding the laws in their particular state, teachers can consider how they might welcome families even when, by legal definition, the family consisting of parents who are LGBTQ may not be defined as a family. Additionally, teachers and administrators need to be aware of any nondiscrimination policies held by their own centers and any funding agencies the center or staff work with as those anti-discrimination policies may include sexual orientation and/or gender identity or expression. If those terms are listed in the policies, it is imperative that teachers understand the implications if they do not adhere to requirements.

There are changes that can be made to the environment to make a welcoming center for families with parents who are LGBTQ. These include putting up pictures of many “types” of families with particular attention to families with two moms, two dads, or parents whose gender is not easy to discern; having developmentally appropriate literature for children in which there are parents who are LGBTQ; having materials in the classroom that depict various family structures including puzzles and dolls (having more than one “mom” doll in the dollhouse area); and being cognizant of the songs they sing and the stories they tell young children (changing words to a song so rather than having a mom and a dad in a song there are two dads). And finally, being careful and sensitive with language will help to welcome parents who are LGBTQ. When forms are developed, there can be spaces for “parent(s)/guardian(s)” rather than “mom” and “dad.” As letters are written home to families the salutation could read “Dear Families” rather than “Dear Mom and Dad.” In the center handbook, there could be a definition of *family* that includes parents who are LGBTQ.

Changes such as the ones just listed will help to welcome LGBTQ parents into early childhood settings. Parents want to know their child(ren) will be well taken care of, and one of the ways we can do this is by welcoming the entire family. Welcoming the entire family includes acknowledging the lived experiences of LGBTQ parents and their children by understanding current legislation within a given state, getting to know the individual families as each has a unique story, and making modifications to clearly invite and welcome families with parents who are lesbian, gay, bisexual, transgender, and queer.

PARTNERSHIP TRANSITIONS

Increases in divorce, cohabitation, and nonmarital childbearing during the past few decades have increased young children's exposure to *partnership instability*, defined as a parent's entrance or exit from a coresidential union (i.e., marriage or cohabitation) or a dating, nonresidential partnership. In turn, exposure to partnership instability has been shown to increase child behavioral problems and interfere with school commitment and success. Partnership instability is especially pronounced among low-income populations and racial/ethnic minorities, suggesting that recent changes in family experiences may be exacerbating race/ethnic and class disparities in children's educational chances.

Partnership instability may also be contributing to the growing gender gap in education. Whereas prior to the 1980s, boys obtained more schooling than girls, today's boys are less likely to finish high school, enter college, and graduate from college than their female peers. Importantly, the widening education gap between boys and girls occurred during the same period as the increase in mothers' partnership instability, suggesting that the two trends may be related. Although boys and girls experience similar levels of exposure to family instability, there is some evidence that boys are more negatively affected by instability than girls. This implies that the increase in family instability during the past few decades may have disadvantaged boys relative to girls.

Early Schooling

Prior research on instability and children's education has focused largely on older children and adolescents. Yet, understanding how partnership instability affects the education of younger children is important. The early years of schooling represent a major life transition during early childhood. As children make the home-to-school transition, they must adapt to a new environment, negotiate new relationships with authority figures and peers, and behave based on a new set of expectations. Successfully negotiating the transition to school is critical because this period has important and long-lasting consequences. Children's experiences and performance at the start of school serve as a foundation for future academic progress and, importantly, launch children into trajectories of achievement. Problems during this critical transitional period, not just academically but also behaviorally, can be devastating. Given the cumulative nature of the curriculum, it is very difficult for children who do not perform well in the early grades to recover from this in later grades. Furthermore, schools' records of academic and behavioral problems follow children across grades and schools, influencing teachers' beliefs and expectations, which in turn affects children's future success in school.

Children's ability to successfully negotiate the move to elementary school plays a major role in their later achievement; yet, research suggests that many children have difficulty transitioning to the intellectual, behavioral, and social demands during this period. For example, boys, racial/ethnic minority children, and children with birthdays late in the school year are more likely to experience learning or behavioral problems during the first few years of formal schooling. Family characteristics that are consistently overrepresented among children with school adjustment problems include low parental education levels, family disruption, single parenthood, and family poverty. Given the growing rate of nonmarital childbearing and family instability, understanding relationship instability and its effects on children's education during this critical period is important.

Partnership Instability and Early Childhood

A wealth of empirical evidence links parental divorce or separation with poor child outcomes, including internalizing problems (e.g., depression and anxiety), externalizing problems (e.g., anti-social behavior), academic problems (e.g., low grades and low scores on achievement measures), and health problems (e.g., obesity). Remarriage is also found to be associated with poor child outcomes. In recent years, the field has responded to the increasingly diverse nature of American families by studying family structure change over time and by incorporating cohabiting and dating relationships into investigations of family instability. Research on elementary school children, in particular, indicates that coresidential (i.e., changes in marital or cohabiting unions) and dating instability predict parent- and teacher-reported behavioral problems. The association between partnership transitions and cognitive outcomes during early childhood is less clear, with some research reporting a significant, negative association and other research finding no association. In studies of cohabiting and dating transitions over time, researchers have also explored the extent to which the timing of transitions matters for young children's behavior and education. Typically, this work investigates differences in the effects of transitions that occurred early in a child's life versus those that occurred recently, often defined as transitions taking place in the past two years. Overall, findings are mixed and more research is needed on the role of proximity for understanding associations between partnership transitions and early child development.

To a large extent, explanations for the association between marital/cohabiting transitions and children's difficulties during early childhood draw on social stress theory. According to this theory, changes in economic, social, and health resources, brought on by changes in family structure, induce stress and diminish mothers' capacity for positive parenting, in turn negatively affecting children's development. Social stress theory also points to the cumulative nature of stressful experiences,

suggesting that parents who undergo one family structure change may be more likely to experience subsequent changes with the effects accumulating over time.

The impact of dating transitions on children may also be filtered through maternal resources and parenting. Indeed, some research suggests that higher levels of dating transitions are associated with higher levels of parenting stress and harsh parenting behaviors among mothers of young children. This may occur because dating reduces time spent with children or disrupts family rules and routines.

The negative effects of partnership instability on young children's education may also be because parents who undergo partnership transitions differ from those in stable relationships, and these differences may be the source of poor child outcomes. For example, a woman who has poor relationship skills may experience more partnership transitions and have children with more academic problems. In this case, the true cause of poor achievement is the mother's relationship skills rather than partnership instability.

Potential Differences by Child Gender

There are several theoretical reasons for expecting boys to respond more negatively to family disruptions than girls. The presence of a male role model may be more important for boys' identity, boys may be harder to manage than girls, or mothers may treat sons differently than daughters because of negative emotions toward the father or because of concerns about their child's safety. Research also suggests that boys may be more negatively affected than girls by disruption in the home. Following a divorce, mother-son relationships are generally more strained than mother-daughter relationships and boys exhibit more short- and long-term behavioral problems than girls. Gender differences in behavior and achievement may be even more pronounced for children exposed to multiple partnership transitions. Insofar as boys take longer than girls to adjust to a family transition, multiple transitions may be particularly problematic for boys.

Conclusion

Extant literature contains a number of implications for policies and programs aimed at strengthening families and improving child well-being. For example, policy makers and program providers need to pay close attention to gender differences in the effects of instability on children's behavioral problems. Several studies indicate that early behavioral problems are strong predictors not only of future behavior but also of educational and occupational attainment. Indeed, much of the success attributed to early childhood education programs is due to reductions in behavioral problems and improvements in social skills. To the extent that family instability has differential effects on boys and girls, the increase in instability during the past few decades may explain some of the growing gender disparity in school achievement.

Additionally, research points to the importance of moving beyond a focus on marital unions to include cohabiting as well as dating unions. The federal Healthy Marriage Initiative, begun during the George W. Bush administration, seeks to promote marriage by providing parents with training in relationships skills. Yet, research suggests that a stronger emphasis on relationship stability, regardless of the type of union, is important for promoting children's education, especially among young boys. Relatedly, policy should more seriously consider the impact that dating relationships have on the well-being of household members. These relationships are often not the focus of policies, but a growing body of evidence highlights the early developmental risks of all forms of partnership instability.

PEABODY PICTURE VOCABULARY TEST

The Peabody Picture Vocabulary Test (PPVT) is a norm-referenced test designed to assess receptive vocabulary skills in children, adolescents, and adults. Though developed for use with a wide age

range, the PPVT is often used in early childhood contexts due to the rapid development of receptive language in early childhood and its relevance to academic and learning outcomes. This entry provides a brief history of the PPVT, a description of the test, and a review of current uses of the test in research and applied settings.

A Brief History of the PPVT

The PPVT has a long and established history in psychoeducational assessment and early childhood education. The original version of the PPVT was published in 1959, followed by a revised edition in 1981 and a third edition in 1997. The most current version is the PPVT, Fourth Edition, published in 2007. This latest revision includes updated pictures in full color, updated norms, and new vocabulary words and illustrations. Most relevant to early childhood assessment, the PPVT-4 includes a greater number of items at the easy end of the scale, with the purpose of improving the test's ability to accurately measure receptive language skills among very young children, children with disabilities, and children with a low level of vocabulary development.

Description of the PPVT

The PPVT is a standardized measure of receptive vocabulary for use with individuals from 2.5 years to 90 years of age. Receptive vocabulary is conceptualized as the ability to receive and understand spoken or written language and may also be referred to as hearing vocabulary, listening comprehension, or language comprehension. This is in contrast to expressive language that involves naming ability and word retrieval skills. For each item on the PPVT, examinees are presented with a page with four pictures. The examiner reads a single word aloud, and examinees are then asked to point to the one picture that best represents the meaning of that orally presented stimulus word. Thus, administration involves the examiner reading the words out loud, and the examinee then simply points to the picture corresponding to that word. The words contained in the PPVT items

include nouns (categories such as animals, body parts, and household objects), verbs (actions), and attributes.

The PPVT is an untimed, individually administered test. There are two parallel forms available (Form A and Form B), each with 228 items in the same format. Examinees do not take all 228 items; they take item sets based on age and appropriate difficulty level. As a norm-referenced test, the PPVT was normed on a large sample of individuals from across the United States. The PPVT provides users with several different types of scores to facilitate interpretation and description of students' performance when compared with same-age or same-grade peers. These normative scores include standard scores, percentiles, age equivalents, grade equivalents, stanines (a scaled test score method), and normal curve equivalents.

Because the PPVT is a standardized test, administration, scoring, and interpretation of PPVT scores should be limited to professionals who have had training in individual assessment using standardized procedures. Following standardized procedures is necessary to produce scores that are reliable and valid, and that lead to meaningful norm-referenced interpretation.

Current Uses of the PPVT

Research studies have used various editions of the PPVT as a measure of receptive language skills among children, adolescents, and young adults with developmental disabilities, communication disorders, Down syndrome, autism, traumatic brain injury, intellectual disabilities, learning disabilities, emotional disturbance, attention-deficit/hyperactivity disorder, low birth weight, genetic disorders, students in gifted programs, and students receiving special education services. In research contexts, the test is often used to study differences in language skills among different groups of children, to examine the relationship between demographic variables (e.g., sex, ethnicity, age) and language functioning, to study the influence of environmental factors (e.g., parental stress, socioeconomic status, exposure to environmental toxins) on language development, to investigate

the development of language using longitudinal designs, and to assess outcomes in intervention studies using pre/post designs.

In clinical and educational practice, the PPVT is used to provide a norm-referenced assessment of receptive language skills for the purpose of identifying children with disabilities, to develop instructional interventions, and to measure growth or progress in language skills over time (e.g., assessing response to instruction). Vocabulary represents acquired knowledge, often gained through reading or exposure to learning opportunities and enriching experiences. Since vocabulary acquisition is strongly correlated with reading comprehension skills, general academic readiness, and general cognitive ability, the PPVT is often used as a screening instrument because it is objective, is relatively quick and easy to administer, and has strong psychometric properties.

Given the range of clinical and research applications, the PPVT is a popular test among school psychologists, educational diagnosticians, neuropsychologists, and speech-language pathologists. The PPVT is often used in conjunction with the Expressive Vocabulary Test (EVT) to provide a comprehensive picture of language function, with the PPVT serving as a measure of receptive vocabulary and the EVT serving as a measure of expressive vocabulary or word retrieval.

PEDAGOGICAL KNOWLEDGE

Pedagogical knowledge might be defined as knowledge of teaching. Understanding teaching requires one to consider the overarching purposes or aims of education. Fundamentally, the purpose of teaching and education more broadly is that the individual(s) being taught learn something as an outcome of the teaching. Teaching might therefore be characterized as the range of activities a teacher engages in as he or she seeks to enhance the learning of his or her students. The challenge of these simple definitions is that teaching itself is so complex. Teaching is an interaction between a teacher and student(s) that requires not just a knowledge base (both content and pedagogical in nature) but also requires the ability to effectively and efficiently apply that knowledge base in the act of teaching with the outcome of supporting student learning.

Therefore, to understand pedagogical knowledge, one must first consider the wide range of activities that characterize teaching. For example, teaching includes any activity that positively influences student learning, such as planning for and implementing instruction, managing the learning environment, and evaluating student learning. Then one has to think about the knowledge and skill needed to productively engage in those teaching activities. Pedagogical knowledge, therefore, is the deep and varied knowledge teachers have about the processes or methods of teaching that, when implemented effectively, support student learning.

Developing sound pedagogical knowledge requires an understanding of cognitive, social, and developmental learning theories. More importantly, effective pedagogy relies upon the ability of the teacher to apply these theories when working with particular groups of children in classroom settings in ways that support the children's learning and development. Within the context of early childhood education (ECE), the National Association for the Education of Young Children (NAEYC) has articulated a vision of effective practice for teaching children from birth through age 8. The framework, known as *Developmentally Appropriate Practice* (DAP), was developed to promote excellence in ECE by providing a set of guidelines for establishing best practice. The framework, grounded in research on child development and learning and in the knowledge base that informs educational effectiveness, identifies five guidelines for effective teaching. These guidelines are as follows: (1) creating a caring community of learners, (2) teaching to enhance development and learning, (3) planning curriculum to achieve important goals, (4) assessing children's development and learning, and (5) establishing reciprocal relationships with families. A knowledge base informs each of these guidelines and has implications for what teachers do, how they do it, and why they do it. Enacting these guidelines relies upon teachers' pedagogical knowledge. This entry will provide an overview of the pedagogical knowledge and skill required of teachers to enact each of the five guidelines of effective teaching.

Creating a Caring Community of Learners

In order to create a caring community of learners, teachers must have an understanding of the role that safety and belonging play in supporting learning and development. In short, the foundation for such a context is consistent, positive, and caring relationships between and among community members. In ECE contexts, teachers must support and nurture caring relationships between teachers and children, between teachers and other adults in the setting

(coteachers, administrators, and children's families), and among the children themselves. A critical feature of a caring community is that all community members are responsible for contributing to their own well-being and the well-being of others in the community. Therefore, while the teacher does not bear sole responsibility for creating and maintaining a positive learning community, it is the teacher who designs and facilitates opportunities that encourage and enhance this responsibility in others. If creating a community of learners is part of the knowledge base of teaching, what then does the teacher do pedagogically?

The teacher creates many opportunities for children to play and work together as they interact with the learning environment and engage in learning activities. First, the teacher establishes a daily schedule and creates the physical environment to ensure that the classroom schedule and arrangement attends to and meets children's physical and emotional needs and safety. The physical environment includes all materials in the classroom, how the classroom is arranged, what materials are available, and how those materials are stored. Additionally, teachers have to consider how classroom materials are managed by deciding which materials are directly accessible to children and which might require more direct teacher supervision. Effective ECE teachers often use the physical arrangement of the classroom and the daily schedule as two ways that they convey clear, consistent, and reasonable limits on children's behavior and activity. This consistency creates a somewhat predictable environment where children, families, and teachers know what is expected and appropriate, which in turn encourages children's autonomy, independence, and self-confidence. Finally, the teacher plans investigations and projects that require collaboration. The teacher interacts with the children and encourages interactions among the children that require them to share their thinking, extend their thinking, and build upon each other's ideas as they work to solve problems while they learn and play. In addition to creating these opportunities, the teacher must also monitor, anticipate, prevent, and redirect behaviors that

interfere with learning or the maintenance of a caring community of learners. Through these processes, teachers also directly and indirectly teach children prosocial behaviors that enable children to positively contribute to the classroom community.

Teaching to Enhance Development and Learning

Teachers must understand that, from a child's birth, the child's family and other caring adults contribute greatly to the child's development and learning. While development (physical, social, emotional, and cognitive) tends to follow predictable patterns, teachers require deep developmental knowledge in order for them to recognize developmental variation across individuals as well as the unique patterns of development within particular children. Using broad developmental understandings, teachers design learning opportunities that are generally appropriate for the age of the children they teach. However, teachers must also apply the specific knowledge of the particular children they teach to design the most effective instruction that supports ongoing development and learning across various disciplines (language literacy, mathematics, social studies, science, art, music, physical education, and health). Teachers also know that children learn best when they actively construct their own knowledge and understanding. Such teachers recognize that children are best able to construct their understanding when they have opportunities to initiate and regulate their own learning and as they interact with peers, teachers, and other adults. Effective teachers strike an appropriate balance between learning experiences that might be considered either *adult-guided* or *child-guided*. In short, adult-guided experiences tend to be those that are explicitly planned and initiated by the teacher. In contrast, child-guided experiences emerge directly from children's own interests and actions. In both cases, the children and the teacher play an active role in learning. In planning teacher-guided experiences, the teacher designs experiences to ensure that children are actively engaged in learning. In child-guided

experiences, the teacher provides strategic support in ways that directs children toward those experiences that best support children's development and learning. If teaching to enhance development and learning is part of the knowledge base of teaching, what then does the teacher do pedagogically?

The teacher must align both child-guided and teacher-guided experiences to the desired goals of the program. Based upon this alignment, teachers implement curriculum reflecting stated goals to support learning and development. In order to best prepare to strategically support child-guided experiences, the teacher must gather information about children that helps to better understand or anticipate each child's interests, needs, and abilities. Such information can be gathered from families and also from the teacher's own interactions with and observations of children. In the classroom, teachers are best able to discover children's interests, needs, and abilities when they incorporate a wide variety of experiences and materials throughout the day and when they give children extended blocks of time to choose materials and experiences.

Often a teacher may have to extend the range of children's interests to achieve broad learning goals. A teacher does this by presenting novel experiences to children and by introducing stimulating ideas, intriguing problems, or counterintuitive hypotheses. These strategies encourage children's exploration of and engagement with ideas. The teacher supports this curiosity by asking open-ended or probing questions, by thinking aloud as a way of subtly directing children's attention to important experiences or observations, or by offering conjectures that challenge children's thinking or help them make connections that enable children to construct meaningful understandings. As the teacher and children interact in these ways, the teacher is ever mindful of targeting strategic support at a level just beyond what the child can do on his or her own.

Planning Curriculum to Achieve Important Goals

The curriculum, whether commercially published or teacher designed, articulates the knowledge, skills, abilities, and understandings children are

expected to acquire. A good curriculum is informed by early learning standards and knowledge of child development and learning. The teacher, however, is the one who brings life to the curriculum as it is enacted in the classroom. To do this well, teachers must know the children in their classrooms since even the best curricula require adaptation for specific groups of children. Teachers must also possess appropriate content knowledge—that is, the knowledge, skills, and abilities that they are responsible for helping children learn. However, in addition to knowing the subject matter they teach (language and literacy, mathematics, science, social studies, the arts, and physical activity), teachers must know the content developmentally. That is, teachers have to know how ideas within a subject area build upon one another, how children understand and think about the content, what aspects of the subject matter children of a particular age are likely to find challenging or confusing, and why particular subject matter concepts are difficult for children to understand. If planning curriculum is part of the knowledge base of teaching, what then does the teacher do pedagogically?

Teachers apply their rich and varied instructional repertoire and their content knowledge to design instruction that achieves important learning goals. In planning learning experiences, teachers consider typical developmental paths that children follow, and the sequence with which subject matter skills and concepts develop. Therefore, teachers design learning experiences that make connections across subject matter areas (literacy, mathematics, science, social studies, the arts) to support children's learning and development across domains (cognitive, emotional, physical, and social). Children learn through their play as well as through formal instruction. As such, teachers plan opportunities for children to learn and play in small groups, large groups, learning centers, and even outdoors. Teachers may utilize direct instruction, engage children in inquiry learning, or use instructional approaches like the Project Approach. Because teachers understand the affordances that each instructional approach provides, they intentionally align learning experiences with the most appropriate learning structure. Children's learning

and development is likely to be enhanced when they have sustained opportunities to explore topics in depth. Therefore, effective teachers draw upon children's interests or introduce them to topics of general interest to children to create a context that nurtures and encourages children's sustained attention over time. Teachers encourage such attention and engagement by providing a variety of ways for children to engage in the same or similar ideas across a set of learning opportunities, by encouraging children to ask their own questions, and supporting children in their efforts to seek answers to those questions.

Assessing Children's Development and Learning

In order for teachers to intentionally plan curriculum that supports children's development and learning, they must know where children are in relation to developmental markers and learning goals. Assessing children's development and learning is important for several reasons. First, teachers use assessment information to inform their planning and teaching to support both individual and group learning. Second, assessment information can be used to evaluate the overall quality of the ECE program and help teachers identify areas for their own professional improvement. Third, assessments in the form of developmental screenings can be used to identify children who may have unique developmental or learning needs. In addition to being knowledgeable of the different purposes of assessment, teachers, informed by learning and program goals, must determine what to assess. Once teachers determine what to assess, they have to consider the best ways to gather information about children's development and learning that enable them to determine where each child is in relation to learning goals and along a developmental continuum. If assessing children's development and learning is part of the knowledge base of teaching, what then does the teacher do pedagogically?

Teachers engage in ongoing, strategic, and purposeful assessment of children's learning and development on a daily basis. One of the most

important assessment skills that provide teachers with insights regarding children's learning is the ability of the teacher to carefully observe children. When observing children, teachers should focus on the processes children use when engaged in learning activities that often provide more useful information to teachers than whether the child was correct or incorrect. Because teachers use assessment information to inform future teaching decisions, teachers must document their observations and gather additional evidence of children's progress toward learning goals to support their teaching decisions. Teachers do this by collecting samples of children's work over time, talking with children to learn more about their thinking, and writing anecdotal notes to record details of and insights regarding children's engagement in learning tasks. An ability to do this well is dependent upon the teacher's pedagogical knowledge in each of the other areas previously elaborated upon above. For example, when talking with children to gain insight into their thinking, the teacher probes children's thinking with intentional and well-timed questions or comments that are informed by the teacher's developmental understanding of the subject matter and designed to elicit a child's thinking about significant elements of the content.

Establishing Reciprocal Relationships With Families

Developmentally Appropriate Practice informed by a teacher's pedagogical knowledge is based on broad developmental principles as well as a teacher's understanding of the broader contexts within which the children they teach live and grow. It is imperative for teachers of young children to acquire much of this knowledge through the productive and reciprocal relationships they actively develop with families. To do this, teachers must understand that families are diverse along a variety of dimensions: composition (single-parent families, blended families, extended families, etc.), culture, economic status, employment and housing status (homeless, unemployed, migrant families, etc.), sexual orientation, and religious beliefs.

In coming to know the families of the young children they teach, teachers must learn about the values of and expectations that each family has for their child(ren). Teachers must also learn about the broader social, cultural, and community contexts within which children live and consider how these contexts shape children's development and learning both inside and outside of the ECE setting. While teachers may gain some of this knowledge by learning about different cultures, the best way to gain such knowledge is experientially. Effective teachers gain such knowledge through the establishment of respectful and reciprocal relationships with families. If establishing reciprocal relationships with families is part of the knowledge base of teaching, what then does the teacher do pedagogically?

Teachers begin by creating a caring community of learners that recognize the children's families as integral members of that community. Families are made to feel welcome in early childhood settings and classrooms. Teachers greet each child and family as they arrive and depart each day, display family photos and artifacts around the classroom, and teachers and families regularly share anecdotes about children with each other. Families view teachers as a resource and advocate as teachers support children and adults through potentially difficult transitions, as a source of information about developmental issues, and links to a range of services outside of the ECE setting. Because the teacher recognizes that families want to be involved in their children's class but that not all are able to volunteer directly in the classroom, the teacher offers families a variety of ways to be involved. For example, parents might help by preparing materials for a class activity at home in the evenings. Finally, teachers and ECE settings schedule regular events for families and children where the teachers, families, and children can engage together as a community. Such events might include potluck dinners, family literacy nights, nature walks, participation in community events, or simply engaging in enriching learning activities that families and children can also easily do at home.

Conclusion

In short, pedagogical knowledge is the deep and varied knowledge teachers have about the processes or methods of teaching. A teacher with deep pedagogical knowledge creates a physical environment that promotes and protects the health and safety of all learning community members. Teachers with deep pedagogical knowledge possesses a rich and varied repertoire of teaching skills and strategies. They know how and when to choose specific strategies to effectively support children's learning and development. Teachers with deep pedagogical knowledge understand how students construct knowledge and acquire skills. They apply this knowledge as they plan and enact curriculum to help children develop habits of mind and positive dispositions toward meaningful learning and the achievement of important goals. Teachers with deep pedagogical knowledge select and use assessment strategies that are appropriate to the developmental and experiential needs of the children they teach. Such teachers use assessment information responsibly to inform future teaching decisions, to make program improvements, and to communicate with a child's family regarding the child's development and learning. Finally, a teacher with deep pedagogical knowledge establishes and nurtures respectful and reciprocal relationships with families. When implemented effectively, such pedagogical knowledge supports children's development and learning.

PEERS AND PLAY

For young children, the principal source of peer interaction occurs during play. In contrast to interactions between older students and adults, who often have exclusively task-oriented reasons to interact, the primary form of interacting for young children is within the bounds of playing together. Dating back to the observations of Greek philosophers, play has been considered characteristic behavior of young children. Indeed, play has often been considered as a process in which children are able to practice the behaviors and skills they need as adults. As such, adults should structure and promote play around experiences that would prepare children for the expectations of the adult world. In this way, play has been considered the child's work. This entry reviews the development of children's play with

peers and highlights the important context of gender within play. It also highlights how adults can promote healthy play.

The Importance of Peer Play

Peer play has increasingly been recognized as having a significant role in children's *social-emotional* and *cognitive* development. For example, child development theorists Jean Piaget and Lev Vygotsky proposed comprehensive theories of children's cognitive development in which play had an integral role. Both Piaget and Vygotsky considered children active constructors of their own learning. Piaget proposed that play was an opportunity for children to practice what they already knew but was not a mechanism for new learning. Vygotsky, on the other hand, considered play—particularly make-believe play with peers—as crucial to building new cognitive and social-emotional knowledge. Vygotsky proposed that when children play with one another, especially with more advanced peers, the exposure to skills currently outside of their reach advances their *zone of proximal development*, a level of ability that can be reached with assistance from others but not alone. Further, peer play was a highly effective format for children to practice and hone language skills, thereby facilitating cognitive advancement.

Play is now also widely regarded as crucial for children's social development. Through play, children experiment with different roles and identities and learn how to navigate social norms, providing opportunities to learn and practice self-control, emotional expression, perspective taking, and conflict resolution, which ultimately help children build and maintain positive relationships with their peers as well as adults. For example, when a group of children decide to operate a make-believe grocery store, if the experience is to be successful, they must be able to listen to diverse ideas as well as to communicate their own, demonstrate self-control when others hinder their plans, and pay attention to and remember the group's agreed-upon parameters about the store.

Developmental Sequence and Types of Play

Social scientists are particularly interested in how, when, and why children choose (or not) to play with each other across the early childhood period. These scientists focus largely on the changing types and priorities in play, noting that play tends to increase in complexity and becomes increasingly peer-oriented as children mature. In the first year of life, infants prefer to explore the immediate environment and maintain close proximity to a caregiver. Research shows that up to 3 years of age, children continue to prefer to play with a nurturing adult nearby in small-scale spaces. When children reach preschool ages (about 3 to 6 years old), their favorite activities involve specific types of play with their friends. However, as children navigate novel non-home settings comprised of unfamiliar children and adults, play without peers may predominate. *Solitary independent* play involves playing by oneself (e.g., painting a watercolor picture). Similar, but distinct, *parallel* play involves engrossed, independent play alongside but not with others, even in the middle of a group and even sharing materials (e.g., building one's own block structure from a community block set).

As children mature, their play increasingly acknowledges and incorporates peers into their play, even when they do not specifically engage in activities collaboratively: *Onlooker behavior* play involves watching or talking to peers engaged in play activities, but not engaging oneself (e.g., standing near and watching other children taking turns sliding down a slide), and *associative* play involves sharing materials and talking to others but not coordinating objectives or interests (e.g., as they share props from the dress-up box, one child discusses plans to put out imaginary fires, whereas another discusses plans to perform as a magician). Toward the beginning of formal school, children tend to prefer play with peers. *Cooperative* play occurs when children engage in activities that require the participation of the group with specific roles, rules, and goals (e.g., playing hide-and-seek and tag games).

Pretend play is a type of play that can involve peers or not. Pretend, or fantasy, play emerges as early as the second year of life but is considered to peak between 3 and 5 years. This ability requires self-awareness, cognitive awareness, and language skills, and is considered uniquely human. Pretend *dramatic* play, moreover, requires skills to construct meaning and imaginative stories, enriched by the presence and participation of peers. Children at the older end of the early childhood spectrum often engage cooperatively in dramatic play (e.g., assigning roles of clown, lion tamer, tightrope walker, and acrobat to play circus). Thus, as children get older, play behaviors become increasingly more social and complex, and they spend less time playing alone or alongside their peers.

The Role of Gender in Young Children's Peer Play

One of the most salient features of children's peer play is their strong preference to play with peers of the same sex. This sex segregation—the separation of boys and girls into same-sex peer groups—is a well-documented phenomenon and is one of the most universal aspects of development. Sex segregation begins around the age of 3 years and increases throughout childhood. By the time children enter preschool, boys and girls show strong and consistent preferences for play with same-sex peers. By most estimates, over half of all young children's peer interactions involve play with only same-sex peers (e.g., girls playing with girls), about 30% involve mixed-sex peers (e.g., girls playing with a group of boys and girls), and less than 10% of peer interactions involve play only with other-sex peers (e.g., girls playing with boys). With age, children's preference for same-sex peer play increases, at least through elementary school.

Same-sex play is most evident when children are allowed to make their own play choices, such as when activities are unstructured and when adults are not immediately present or engaged in children's play (e.g., outdoor free-choice recess). Moreover, these preferences are difficult to change. For instance, teachers can increase the amount of other-sex play by providing reinforcement for such

interactions. However, when the reinforcement is no longer available, children quickly return to baseline levels of segregated play.

Early childhood peers actively influence each other's behaviors, attitudes, interests, abilities, and motivation, and playing with boys provides different opportunities and experiences from playing with girls. Boys tend to play in larger groups, in more public places, and with less proximity to supervision than do girls. Boys' play also tends to be rougher and more active than girls' play, and more often involves physical contact and fighting. Boys quickly establish a hierarchical order that tends to remain stable over time. In contrast, hierarchies in girls' groups are more fluid. Girls often emphasize cooperation and verbal interaction among play partners and use enabling forms of communication that promote group harmony. Compared with boys' groups, girls' groups are more likely to select activities that are structured by adults and that are governed by strict social rules.

Experiences gained within boys' and girls' peer groups promote different behavioral norms and interaction styles. Over time, repeated exposure to these different norms and interaction styles lead to the development of different skills, attitudes, motives, interests, and behaviors. For example, patterns of behavior and attitudes that are commonly thought of as being boylike (e.g., "he's so strong") or girllike (e.g., "she's so graceful") may be the result of boys playing with boys in boylike ways, and girls playing with girls in girllike ways. Additionally, same-sex peer play sets the stage for considering other-sex peers as less desirable, promoting bias and exclusionary attitudes. In this way, children's early sex-segregated peer relationships appear to set the stage for sex differences and stereotyped behavior and attitudes. Importantly, these effects are *dosage dependent*, meaning the more time children spend playing with same-sex peers, the stronger the socializing effects become. Moreover, the effects are seen relatively quickly. Some evidence suggests that the effects can occur in a just a few months of time at school. As such, young children's same-sex peer play groups represent a powerful context for socialization.

The potential consequences produced by early sex-segregated play groups are significant for development not only in childhood but considerably beyond, when children converge as teens and adults. Several scholars have argued that boys and girls grow up in different social worlds and that the different social histories of males and females that likely originate in the context of young children's same-sex play affect the relationships of heterosexual couples and the nature of cross-sex interactions that occur in the home and in the workplace.

Early Childhood Contexts That Promote Play and Learning

As described, play serves a number of varied purposes and has important implications for children's healthy developmental. Adults sometimes view play as the opposite of learning, because it appears less work oriented than a stereotypical lesson. However, this is a false dichotomy: Play is the foundation of young children's learning.

To maximize the learning benefits associated with play, young children need environments that are conducive to varied types of play including with diverse groups of peers, as well as teachers who facilitate play in developmentally appropriate ways. Children need physical space and structures, such as large blocks of time that allow them to initiate and direct play and to explore materials that interest them. Children are attracted to sociodramatic play materials associated with real-life scenarios and roles they can relate to or are learning about, such as trips to the doctor's office, eating out at a restaurant, planting a garden, or being dinosaurs. They are also drawn to play opportunities that allow them to practice developing fine and gross motor skills such as balancing objects (e.g., building blocks), climbing (on play structures), and drawing. When children know where to find play materials and what materials are available to them in prepared environments (e.g., through labeling of play areas and storing materials in clear bins), they are better able to take full advantage of creative play opportunities.

Opportunities for unstructured, child-directed play are important, but adult facilitation can enhance the learning that occurs during play. For example, adults can structure play opportunities around specific learning goals. If children are learning about various professions, adults might set up play stations that allow children to enact roles as bakers, scientists, or teachers. Adults can also promote children's use of language and higher order thinking skills during play activities. By posing open-ended questions, asking children to make predictions pertaining to various scenarios, and integrating advanced and varied vocabulary in conversations with children, adults promote children's capacity for expressive language as well as their ability to think more abstractly about ideas emanating from play.

Adults' facilitation of children's play is also important to enhance the potential for social learning through play. For example, an adult may guide a shy child in initiating play with peers, or conversely, help a child adept at taking charge to accept peers' directions. Adults can create opportunities for boys and girls to play together when they may otherwise gravitate toward same-sex play. Group play is also a prime opportunity for adults to help children resolve conflicts when disputes arise. Because play is also enjoyable, experiences and environments involving play become associated with people, places, and things children enjoy. This suggests the importance of play in early development as a means to promote children's positive feelings toward school. In summary, when adults are purposeful in the way they structure a child's day and interactions with peers, development, learning, and well-being can be greatly enhanced.

PERSONNEL PREPARATION FOR EARLY INTERVENTION

Personnel preparation refers to an organized program of study that prepares individuals for careers. The focus of this entry is on preparation of teachers for early intervention. Teacher preparation programs generally include both coursework and field-based experiences.

Teacher preparation is generally thought of as occurring at the preservice or in-service level. Preservice preparation refers to the program of study and training that occurs prior to taking a teaching position. In-service refers to coursework or training for those who are already engaged in the profession of teaching. This is an artificial distinction in early intervention in that many individuals take on the role of teacher before they have completed a formal personnel preparation program. With increasing requirements for college degrees and demonstration of performance competencies, more teachers are completing preparation programs while they continue their employment. They will then advance their knowledge and skills

through ongoing participation in in-service learning activities. The competencies and professional standards described below are relevant guides for both preservice and in-service programs.

Context

Historically, teachers of young children entered the workforce with limited formal preparation but an eagerness to work with young children and foster their development and learning. In the latter half of the 20th century, there was increasing awareness of the importance of teacher preparation to ensure that teachers had an understanding of child development and learning and other important areas of knowledge.

It is now established that a necessary ingredient for the design and delivery of high-quality education and care for young children is a well-prepared workforce. The workforce must have the requisite knowledge and skills to use evidence-based practices that promote positive outcomes for children and support for their families. In this era of accountability, there are high expectations for teacher candidates as they complete preservice preparation programs. These expectations appear as professional standards that are rigorous and measurable. The intention is that personnel preparation programs ensure that candidates possess and demonstrate these standards—the knowledge, skills, and sometimes, dispositions needed to effectively guide and teach young children.

Professional Standards

Professional associations have a commitment to policies that support development and renewal of professional standards. Colleges and universities use the standards to design, implement, and evaluate preservice preparation programs as well as advanced degree programs.

The National Association for the Education of Young Children (NAEYC), the major professional organization for early education and care professionals in the United States, outlines six professional standards. These standards and explanatory

statements are organized into the following areas: (1) promoting child development and learning, (2) building family and community relationships, (3) observing, documenting, and assessing to support young children and families, (4) using developmentally effective approaches to connect with children and families, (5) using content knowledge to build meaningful curriculum, and (6) becoming a professional. The standards, published in 2010, were developed through a multistep process that incorporated current research and expert knowledge. The content areas of the standards are appropriate across associate, bachelor, and advanced degree levels.

The Council for Exceptional Children (CEC) and its relevant division, the Division for Early Childhood (DEC), recognizes that use of evidence-based practices in the education and care of young children with disabilities and other special needs is essential for children to reach their potential. These organizations have ongoing processes to update and disseminate professional standards for beginning and advanced teachers. CEC's most recent version of the professional standards for special educators are organized into seven areas: (1) learner development and individual learning differences, (2) learning environments, (3) curricular content knowledge, (4) assessment, (5) instructional planning and strategies, (6) professional learning, and (7) collaboration.

DEC develops and validates professional standards that are based on the CEC standards and then specialized for early intervention/early childhood special education. The current set of early childhood standards are based on the slightly earlier set of 10 CEC school-age standards. Since 1993, DEC and NAEYC have worked together to present professional standards that are aligned for the workforce and yet address the needs of diverse young learners including those with disabilities. The initial Early Intervention and Early Childhood Special Education (EI/ECSE) special set of professional standards are endorsed by DEC and NAEYC. DEC undertook a process to align the DEC standards with the NAEYC standards. The analysis showed greatest agreement in the areas of

partnering with families, collaboration, and content knowledge. There was weakest agreement in the area of instructional strategies. This makes sense in that the DEC standards are specifically intended to clarify the specialized knowledge and skills required to meet the needs of diverse learners. Further, the alignment or agreement of most content areas bodes well for inclusive programs in which teachers guide the development and learning of children with and without disabilities.

Both NAEYC and CEC now have newer, revised versions of their professional standards. A rigorous process is in place to update the EI/ECSE specialty set of standards for young children. This process includes representation from DEC, NAEYC, and the Early Childhood Personnel Center (funded by the U.S. Department of Education), and new alignment of standards is expected in late 2015.

In addition to college-level preparation leading to a bachelor's or advanced degree, the Child Development Associate (CDA) credential is recognized as an entry-level qualification for some early learning programs such as child care and Early Head Start. The credential is based on a core set of standards that students meet through coursework, experiences, presentation of a portfolio, and an exam. The Council for Professional Recognition administers the credentialing program. The subject areas are (a) planning a safe, healthy learning environment; (b) advancing children's physical and intellectual development; (c) supporting children's social and emotional development; (d) building productive relationships with families; (e) managing an effective operation; (f) maintaining a commitment to professionalism; (g) observing and recording children's behavior; and (h) understanding principles of child development and learning.

The Institute of Medicine, National Research Council recently published the newest set of knowledge and competencies for the early childhood education field. An expert committee of researchers identified this set of knowledge and competencies based on the latest research. The competencies are organized into a set of foundations for all adults with professional responsibilities for young children. These appear as knowledge

areas (development and learning, relationships and learning opportunities, support and stress factors) and skills areas (engage in interactions, promote social development, observation and screening, and awareness of technology to support learning). The next set is the specialized knowledge and competencies needed by care and education professionals who work directly with young children. More specific knowledge and competencies are organized into five areas: (1) core knowledge base, (2) practices to help children learn, (3) working with diverse populations of children, (4) developing and using partnerships, and (5) continuously improving the quality of practice.

These sets of competencies and professional standards show some similarity. They also show the growing recognition that early childhood educators are professionals who have a recognized knowledge base that is founded on scientific research. To achieve the goal of high-quality education and care for young children, it is expected that teachers will demonstrate these competencies.

Accreditation

In the 1990s, some personnel preparation programs began to consider and develop preparation curricula that blended both general early childhood and special education content and led to dual certification. As states began to recognize this option, DEC, CEC, and NAEYC collaborated in order to guide and support the effort. One outcome was approval by the National Council for the Accreditation of Educator Recognition (NCATE, now the Council for the Accreditation of Educator Preparation [CAEP]) for the joint review of early childhood proposals for accreditation. CAEP is the accrediting body for educator preparation programs in the United States.

For the most part, colleges and universities have the responsibility for preparing early childhood educators with sound coursework and field-based learning opportunities. Personnel preparation programs provide learning opportunities that are aligned with the standards and competencies, assess teacher candidates on their demonstration

of the competencies, and assure the certifying or credentialing agency that teacher candidates meet the professional standards. While the CDA is administered by a private organization, teacher certification is administered by states. Most states use the professional standards described by professional organizations as the basis for their awarding of certification.

Finally, colleges and universities have the responsibility for the design and delivery of high-quality personnel preparation programs. While the demand for highly qualified early childhood teachers with at least a bachelor's degree has grown in recent years, there are barriers for current and future teachers who desire a quality program. The barriers include lack of access to nearby colleges, lack of affordable programs for teachers who work in a field with relatively low salaries, lack of relevance to early childhood (i.e., some colleges offer only elementary education majors rather than providing an early childhood focus), and lack of effectiveness (i.e., the link between the preparation program and child outcomes is not known). However, with increased demand, increased attention by researchers and policy makers on early intervention for all children, and innovations in both in-person and online programs, the quality of personnel preparation programs is expected to grow.

PHONOLOGICAL ABILITY

Phonological ability is a skill set necessary for reading and spoken language. Specifically, the ability to hear, process, produce, and manipulate speech sounds (also called *phonemes*) contribute to a child's ability to learn to decode words as well as produce age-appropriate speech sounds. This entry provides information about typical phonological ability as well as several suggestions for appropriate assessment and early intervention for children who are assessed as having delayed phonological ability.

Overview

Phonological ability can be explained broadly in two ways: receptive skills and expressive skills. Receptive phonological skills comprise phonological awareness, phonological working memory, and phonological retrieval. First, phonological awareness is the explicit knowledge of the speech sounds within the language. Rhyming is a common example of a phonological awareness task. The ability to rhyme showcases a child's knowledge of phonological similarities (e.g., “rat” and “mat” sound the same at the end of the word). Often, preschool-age children have the capacity to rhyme—either by identification tasks (e.g., “Tell me which word rhymes with *cat* . . . *may*, *man*, *mat*”) or production tasks (e.g., “Tell me a word that rhymes with

‘sun’”). By school age, it is expected that children are able to perform more complex tasks that tap into phonological awareness. For instance, deletion tasks require children to remove one unit from a word (e.g., “say ‘cowboy’ without ‘cow’; say ‘cat’ without the /k/ sound). Second, phonological working memory tasks require a child to retain phonological information in a limited capacity memory space, manipulate it in some way, and reproduce it. As an example, a number reversal task requires that a child listen to a list of numbers, mentally rearrange the order of the numbers, and produce the list of numbers in reverse order. A common way that phonological memory is often measured is through the use of a nonword repetition task. Such a task requires children to listen to an increasingly complex list of nonwords (i.e., words that follow the phonological patterns of English but do not have meaning in English) and repeat them. Children who struggle with this type of task are often at risk for struggling with reading. Third, phonological retrieval is a skill that requires children to name pictured objects or colors, sometimes in a timed fashion to gauge their access to phonological forms. Simple naming tasks, such as naming the letters of the alphabet, the colors of the rainbow, or common animals, require phonological retrieval, among other language-based skills.

Expressive phonological skills refer to accurate speech sound production. It is very common, early in language development, for children to make particular substitutions during speech sound production. For example, certain phonemes, such as /r/ as in “rain” or “th” as in “thumb,” are more difficult to produce; children may produce these words as “wain” or “fum.” Over time, and by the age of 8, it is expected that children will appropriately acquire correct production of all phonemes. By the age of 3, it is expected that approximately 75% of what a child says can be understood by familiar communication partners. This increases to 90% by age 5. Still, some children struggle with accurate production of speech sounds, putting them at risk for later reading and academic difficulties.

Theory

One common theory that supports the acquisition of phonological ability is the idea of phonological representations. Phonological representations are the means by which phonological information is stored in memory. It is theorized that these representations grow over time through exposure to the necessary phonological information (e.g., through hearing the ambient language, being read to, etc.). For individuals who struggle with phonological ability—such as those with dyslexia, or those with speech sound disorders—it is hypothesized that their phonological representation is weak or underspecified.

Research

Phonological ability is crucial to the growth of reading skills in young children. Children who struggle with phonological awareness tasks often later struggle with word decoding—a necessary piece of successful reading. Phonological ability supports reading by helping to build letter–sound correspondences—the skills needed to learn that alphabet letters not only have names but also make specific sounds. The complex ways that letter sounds change depending on their surrounding letters is a crucial skill necessary for reading. As an example, the letter *C* might sound like /k/ or might sound like /s/ depending on the context. *C* takes on a different sound when it is near *H*, as in *cheese*, or makes no sound at all, in the word *yacht*. Additionally, learning how to synthesize decoded sounds into words takes practice and helps to build “sight words.” Through this practice, children with strong phonological ability learn more new words over time and develop proficient reading skills. Phonological ability can, and should, be assessed in young children to gauge their risk for reading disabilities. This is especially true for young children who have expressive phonological disorders (e.g., difficulty producing speech sounds). Using some of the tasks listed here (e.g., rhyming, phoneme deletion, nonword repetition), teachers or clinicians can obtain useful information about a child’s phonological ability. Extensive

research has shown that this skill can be taught to preschool and school-age children through explicit and systematic instruction. As such, early identification and intervention is key to the prevention and/or remediation of reading difficulties.

PHYSICAL DISABILITIES

Physical disabilities are severe orthopedic impairments that influence a child's gross motor (large muscles) development and/or fine motor (small muscles) development. Physical disabilities often have a negative influence on a young child's ability to participate with other children in social or educational settings. In the United States, physical disabilities are referred to as "orthopedic impairments" under the Individuals with Disabilities Education Improvement Act (IDEA). This entry provides information about categories of physical

disabilities found in young children, the types of support young children with physical disabilities need, and how children in early childhood settings are served through interdisciplinary teams of professionals.

Categories of Physical Disabilities

Physical disabilities can be divided into three main categories. These include (1) neuromotor differences, (2) musculoskeletal disabilities, and (3) degenerative disorders.

Neuromotor Differences

Neuromotor differences are the result of damage to the nervous system, spinal cord, or brain and are most often present before or during birth. Neuromotor differences may result in complex motor difficulties. Two of the most common neuromotor disabilities are *spina bifida* and *cerebral palsy*.

Spina bifida is characterized by a developmental difference in the spinal column that occurs during prenatal development. Paralysis often results. The level of paralysis depends on the severity of the condition and intellectual ability may or may not be affected. *Spina bifida cystica* is the most severe type of spina bifida while *spina bifida occulta* is the milder form.

Cerebral palsy results from damage to the motor control area of the brain. This can occur before, during, or after birth. However, many children develop cerebral palsy during birth because of a long and difficult labor. Children with cerebral palsy may have hypertonic muscle tone (stiff or tight muscles) or hypotonic muscle tone (flaccid or floppy muscles). Cerebral palsy can cause difficulties in mobility (e.g., crawling, walking). Another way to characterize cerebral palsy is by the number of affected limbs (i.e., arms and legs). *Paraplegia* refers to limitations or difficulties in the legs, while *diplegia* means that all four limbs are affected but the legs have more difficulties than the arms. *Quadraplegia* indicates that both arms and legs are affected and have impaired movement or limitations, while *hemiplegia* means that either the right

or left side of the body is affected or has impaired movement or limitations.

Musculoskeletal Disorders (MSD)

Musculoskeletal disorders (MSD) represent a category of several conditions involving muscle tendons and joints that result in physical limitations. An example of musculoskeletal disorders is *juvenile idiopathic arthritis*, also known as *juvenile rheumatoid arthritis*. Juvenile idiopathic arthritis usually manifests in childhood any time before 1 year of age to 16 years. There are several types of juvenile idiopathic arthritis that include oligoarthritis, enthesitis-related arthritis, psoriatic arthritis, polyarticular arthritis, systemic arthritis, and undifferentiated. In most cases, the symptoms are swelling and joint pain. The cause is thought to be related to an autoimmune disorder. Other musculoskeletal disorders include problems with the position or shape of a child's legs, feet, or knees. The causes of some musculoskeletal disorders are burns, broken bones, or other maladies that result in damage to the bones or muscles.

Degenerative Disorders

Physical disabilities caused by degenerative disorders result from diseases that increasingly affect physical development. *Muscular dystrophy* is one of the most common degenerative diseases in young children. Muscular dystrophy is a genetic disorder that gradually weakens muscles involved with mobility. These muscles become weaker over time, resulting in diminishing motor abilities and the degenerative nature of the disorder. There are numerous types of muscular dystrophy, the most common being *Duchenne*. Other forms include *congenital muscular dystrophy*, *myotonic*, *facioscapulo-humeral*, and *limb-girdle muscular dystrophy*.

Education

Young children with physical disabilities receive education and special services through the Individuals with Disabilities Education Improvement Act (IDEA) in the United States. The Division

of Early Childhood (DEC) of the Council for Exceptional Children (CEC) has published the research on evidence-based practices for children with disabilities, including children with physical disabilities. This research and guidelines for educating young children with physical and other disabilities can be found in *DEC Recommended Practices in Early Intervention/Early Childhood Special Education* (2014). Evidence-based practices include appropriate assessment, child-focused instruction, family-based services, and teaming and collaboration. Further, recommended practices suggest that young children with physical disabilities should be included in general early childhood programs whenever possible. Instruction and support, including physical therapy, occupational therapy, speech-language therapy, and other services, should be implemented in the natural environment of young children, which may be in the home, child care, preschool, public school, or other community settings. Routine-based activities within the context of natural environments are recommended for children with physical and other disabilities. Professional support and related services should be provided through collaboration with the family and other professionals in natural environments and inclusive settings. Finally, with regard to education, there have been many studies that report the benefits of early intervention and early childhood special education for young children with physical disabilities. In order to provide benefits for children with physical disabilities in educational settings, however, there is often a need for special equipment or materials, environmental adaptations, and specific considerations for intervention and instruction.

Support

Children with physical disabilities often require *physical therapy* and/or *occupational therapy*. Physical therapy involves help with gross motor skills and mobility (walking or moving). Physical therapists often assist children with orthopedic impairments with sitting, positioning, transferring, and moving from place to place. Physical

therapists may recommend wheelchair support, orthopedic devices, or other equipment to help a child with mobility. They may also recommend special devices to help the child sit, stand, or support the body, especially when participating with other children in group activities.

Occupational therapy is about self-care skills, such as dressing, eating, bathing, and toileting. Occupational therapy also involves fine motor skills required of a child when using writing implements such as crayons or pencils when learning to write or paintbrushes for craft activities. Occupational therapists may suggest a special implement for writing or a device for gripping a crayon or a pencil. They may recommend adapted cups or eating utensils to help a child with a physical disability develop independence and support when eating. Velcro, large zippers, or other equipment may be recommended by the occupational therapist to help a child with dressing and undressing.

Speech-language pathology is another support that some students with physical disabilities need. For example, some children with cerebral palsy require speech therapy. Because cerebral palsy is the result of damage to the motor control area of the brain, the muscles involved in speech often are affected. Children with degenerative muscle problems will probably need speech-language pathology as the muscles continue to weaken over time and influence the children's speech.

The Need for Special Equipment and/or Materials

Assistive technology includes any item, equipment, or system that increases, maintains, or improves functional capabilities of individuals with disabilities. Children with atypical muscle tone (both hypotonic and hypertonic) often require seating and positioning support or equipment. Orthotic devices to facilitate lower body support and movement or prosthetic equipment to improve access to the environment or use with ambulation are sometimes necessary. Children with limited muscle strength may need

adaptations that help with manipulation. Special scissors, drinking cups, spoons, and grasping devices help some children participate in classroom activities and feed themselves. Velcro straps can be used to help with dressing, while other equipment is needed for positioning, lifting, carrying, and transitional experiences such as moving from one activity to the next (e.g., classroom group activities to outdoor activities on the playground). Physical and occupational therapists should be consulted to make sure that special equipment and materials are optimal, are used appropriately, and are the most appropriate for ensuring the child's full participation in daily living, social experiences, and educational opportunities.

Adaptations at Home and School

Because many children with physical disabilities often use assistive technology, the physical environment in the home, school, and community settings should be prepared for maximum accessibility. Assistive devices are designed to promote independence and help the children focus their attention. Those who use walkers, wheelchairs, and other mobility devices need adequate space for ambulation and interactions with adults and other children. Child-size railings and ramps often are used to facilitate movement. Adapted seating and work surfaces help provide access for the children who need such adaptations. Materials also should be readily available at children's eye level and reach that are prepared specifically to accommodate their range of motion.

Because a major goal for children with physical disabilities is to achieve independence, placing objects such as food and toys within easy reach of a child with physical disabilities is a major consideration. Seating and positioning devices are sometimes used to promote appropriate muscle tone and aid in physical development. Numerous seating options that may include wedges, pillows, adaptive chairs, and other apparatuses should be available in home, school, and other environments.

Special Considerations for Early Childhood Education/Instruction/Intervention

For children with physical disabilities who have communication, intellectual, or social needs, adaptations to the environment may require the use of educational and assistive technology that facilitates communication, learning, and interaction with peers. Educational and assistive technology can reduce the impact of children's impairment on their capacity to participate in the learning environment.

Fatigue is a common experience for children with physical disabilities. Families, teachers, and therapists work together to examine and plan appropriate schedules for young children with physical disabilities that are appropriately challenging but not excessively stressful. Transitions from one activity or location to the next may exacerbate stress and fatigue if transitions are not given enough consideration or time. Teachers, therapists, and family members should discuss the nature of transitions in the classroom or home, the time-frame necessary to make transitions, the need (or lack of need) for certain transitions, and the specific support the child with physical disabilities needs to accomplish transitions.

Children with physical disabilities in inclusive settings can experience peer support during transitions; however, this should not be considered one-way support. Young children with disabilities also should be given responsibilities for contributing and interacting with their peers during transitions and classroom activities. For example, a child who has a walker with a basket can be asked to carry simple materials from one place to the next. Professionals and families may need to examine their approach to addressing the needs of children with physical disabilities, considering whether they exhibit expectations that are inappropriate or overprotective behaviors.

Conclusion

Young children with physical disabilities are individuals with "orthopedic impairments" under the Individuals with Disabilities Education
